

Polymorphic Records for Dynamic Languages

GIUSEPPE CASTAGNA, CNRS - Université Paris Cité, France

LOÏC PEYROT, IMDEA Software Institute, Spain

We study *row polymorphism* for records types in systems with set-theoretic types, specifically, union, intersection, and negation types. We consider record types that embed row variables and define a subtyping relation by interpreting record types into sets of record values, and row variables into sets of rows, that is, “chunks” of record values where some record keys are left out: subtyping is then containment of the interpretations. We define a λ -calculus equipped with operations for field extension, selection, and deletion, its operational semantics, and a type system that we prove to be sound. We provide algorithms for deciding the typing and subtyping relations, and to decide whether two types can be instantiated to make one subtype of the other.

This research is motivated by the current trend of defining static type systems for dynamic languages and, in our case, by an ongoing effort of endowing the Elixir programming language with a gradual type system.

CCS Concepts: • **Theory of computation** → Type theory; • **Software and its engineering** → Polymorphism.

Additional Key Words and Phrases: subtyping, union types, intersection types, record types, row polymorphism

1 Introduction

The goal of this work is to define and study *row polymorphism* for a type system with set-theoretic types, in particular, union, intersection, and negation types. Row polymorphism was originally introduced by Rémy [41, 42], Wand [47, 48] and further studied and developed in several works (e.g., [24, 31, 35, 45]). However, as we argue in this work, the theories in the current literature—which use algebraic approaches—cannot be reused for systems with set-theoretic types and, hence, an original theory must be developed. More broadly, the primary conceptual contribution of our work is demonstrating that row polymorphism is not limited to syntactic or algebraic approaches. Instead, it can be effectively integrated into the semantic subtyping framework using the same three conceptual steps employed to incorporate parametric polymorphism into the framework [10, 11].

The interest of developing this new theory is grounded in practice. There is a growing effort to develop type systems for dynamic languages: TypeScript [34] and Flow [18] are two major examples of such an effort and, as most of the existing attempts to add type systems to dynamic languages, they include union and intersection types to accommodate the flexible programming patterns prevalent in such languages. In particular, some widely used dynamic programming languages—such as Lua [30, 40], and Elixir [15]—have embraced set-theoretic types as defined in the *semantic subtyping* framework by Frisch et al. [22]. There, (i) types are interpreted as sets of values, (ii) unions, intersections, and negation types are interpreted as the corresponding set-theoretic interpretations, and (iii) the subtyping between two types is defined as set-containment of their interpretations. Since semantic subtyping is the framework that we use here, our work can

<https://doi.org/10.1145/3720497>

be considered as a study on adding row polymorphism to Luau and Elixir. In particular, the rest of this section uses Elixir’s syntax to showcase practical motivations.

For space reasons, several examples, definitions, and all proofs are omitted. They can be found in the appendixes available in the full version of this work and in the Auxiliary Material section of the ACM Digital Library entry for this work.

1.1 A Motivating Example

To show the interest of having row polymorphism in dynamic languages, let us consider the `logger` module of Elixir’s standard library, which exports the following function (see [17]):

```

1 def add_elixir_domain(x) do
2   case x do
3     %{domain: y} when is_list(y) -> %{x | domain: [[:elixir] | y]}
4     _ -> Map.put(x, :domain, [[:elixir]])
5   end
6 end

```

This code snippet defines the function `add_elixir_domain`, whose argument, bound to `x`, is matched in a case expression. The argument must be a record value (in Elixir records are delimited by curly brackets prefixed by the “%” symbol).¹ If it is a record with (at least) a field for the key `:domain` whose content is a list (line 3), then the function returns a copy of the argument in which the field with key `:domain` is updated by consing the atom² `:elixir` to the list in the argument. Otherwise, (line 4), the function adds (if absent) or replaces (if present but does not contain a list) in the record `x` a field `:domain` whose content is the singleton list whose only element is the atom `:elixir` (this is performed by the function `Map.put` of Elixir’s standard library).

Elixir’s type system [8, 16] features record types without row polymorphism. Hence, the function `add_elixir_domain` can be given this type (the symbol `$` is used to introduce type signatures [8]):³

```

7 $ %{...} -> %{..., domain: list(term())}

```

In Elixir, record types starting by `...` are “open”, that is, the values of these record types may define other fields besides those specified in the type. Therefore, the type above states that `add_elixir_domain` is a function that accepts any record value (since `%{...}` is the top record type) and returns a record with at least a `:domain` field that contains a list of values (in Elixir `term()` is the top type, which types all values, so `list(term())` is the type of all lists; following the Erlang convention, type names are post-fixed by `()`, e.g., `integer()`, `term()`, ...).

The problem with such a type is well known: the type does not specify that the fields corresponding to the ellipsis in the result are the same as those in the argument. Thus, any static knowledge of these fields is lost after the application. The practical consequence of this loss is that an expression such as `add_elixir_domain(%{file: "foo.txt", line: 42}).line`, which tries to select the field `:line` in the result of the application, is rejected by the type checker despite being correct. This hinders the applicability of the type system to existing code and obliges the programmer to resort to the less precise gradual typing features of Elixir’s type system.

¹For consistency, we follow Hoare’s original terminology [28, 29], and always use the term “record” to denote finite key-value maps. In contrast, Elixir uses the word “maps” for finite key-value maps and reserves “record” for a different concept.

²Atoms are user-defined constants prefixed by a colon and of type `atom()`. Field keys are atoms, too, in which the starting colon can be omitted if the field is not optional (see later on): `%{domain: 42}` has a field with key `:domain` and value 42.

³Record types were added in Elixir’s 1.17 release, while “\$” and type variables are planned for latter releases: [16]. Elixir’s syntax for row variables (cf. code in line 8 and on) is not fixed yet: the notation `%{...f, }` is also being considered.

The solution to this problem is also well known, and resorts to using *row variables*, which are variables that range over “rows” of fields of a record type. For Elixir, this would correspond to extending the current type system so that `add_elixir_domain` could be typed as follows:

```
8 $ %{f} -> %{f, domain: list(term())} when f: fields()
```

where `f` is a *row variable*—as stated by the post-fix declaration `f: fields()` (in Elixir, type variables are post-fixedly quantified by a `when` declaration)—which, intuitively, ranges over all fields not already specified by a record type `f` occurs in (here, all fields but `:domain`). Now, when typing the previous expression `add_elixir_domain(%{file: "foo.txt", line: 42}).line`, the row variable `f` can be instantiated to include the two fields for the keys `:file` and `:line` in the argument, enabling the system to deduce for the expression the type `integer()`.

The type system for Elixir defined in [8] also features union, intersection, and negation types—denoted by `or`, `and`, and `not`—as well as polymorphic type variables. Combined with row polymorphism, they refine the previous type of `add_elixir_domain` as follows:⁴

```
9 $ (%{f, domain: list(a)} -> %{f, domain: list(atom() or a)}) and
10 (%{g, :domain => not(list(term())) -> %{g, domain: list(atom())})
11 when a: term(), f: fields(), g: fields()
```

The type above uses the whole palette of set-theoretic types. It also uses both parametric and row polymorphism, since the type features a type variable `a` and two row variables `f` and `g`, as stated by the `when` declaration in line 11. The combination of these two features renders a more precise description of the behavior of `add_elixir_domain`:

- The arrow type in line 9 states that when `add_elixir_domain` is applied to a record value formed by a field `:domain` that contains a list of `a` elements, and by some other fields captured by `f`, then the function returns a record that is of the same type as the argument except in the `:domain` field that now contains a list of “`atom() or a`” elements (union type).
- The arrow type in line 10 specifies as input type a record type with an optional field (denoted by “`=>`”)⁵ of type `not(list(term()))`. Thus, the function type in line 10 types functions that when applied to values in which the field `:domain` is either absent or bound to a value that is `not` a list (negation type), then it returns a record where the `:domain` field contains a list of atoms and, thanks to the row variable `g`, where the other fields of the argument are preserved.
- The two arrows above are connected by an intersection (the `and` connective at the end of line 9) meaning that the function has both types and, thus, obeys both specifications.

If `add_elixir_domain` is given the type in lines 9–11 and if `x` is defined as:

```
12 x = add_elixir_domain(%{domain: [41, 43], file: "foo.txt", line: 42})
```

then the type deduced for the expression `[x.line | x.domain]` is `list(atom() or integer())`.

It is out of the scope of this work to explain why the precision allowed by set-theoretic types is necessary to the typing of dynamic languages. For such an explanation, we invite the reader to refer to [8] which treats the case of Elixir. We want nevertheless to stress the importance of negation types for a precise typing of pattern matching. This is shown in line 4 of the definition of `add_elixir_domain`, where the type deduced for the variable `x` occurring in that line is obtained by

⁴Such a refinement can also be done without row variables, but the problem with forgotten fields is still the same.

⁵A record type such as `%{:bar => t()}` means that in the values of this type, a field for the key `:bar` may be absent, but if present it must contain a value of type `t()`. This is Erlang’s Typespec syntax: in Elixir the keyword `optional` is mandatory, as in `%{optional(:bar) => t()}`, but we omit it to streamline the presentation.

removing, by a negation type, from the type of the input the type of all the values captured by the preceding pattern occurring in line 3.

1.2 The Need for Row Polymorphism

Before delving into the necessity of a new theory of row polymorphism for records, we might first question whether row polymorphism is needed at all. The system we intend to extend already incorporates first-order (*a.k.a.* prenex) polymorphism alongside set-theoretic types. This combination suffices to encode a limited form of bounded polymorphism *à la* Fun [5], which was employed to type polymorphic records. Additionally, Castagna et al. [12] demonstrated that semantic subtyping with polymorphic types is enough to capture polymorphic variant types, which are usually typed by row polymorphism since, in these specific cases, they are dual of polymorphic record types.

In terms of records, the combination of prenex polymorphism and set-theoretic types can be used to type the following function without losing the static information of the fields of the argument:

```
13 def bump_counter(x), do: %{x | counter: x.counter+1}
```

This function increments the `:counter` field of its argument and can be typed by bounded polymorphism by the type $\forall(\alpha \leq \{\dots, \text{counter} = \text{integer}()\}) . \alpha \rightarrow \alpha$. The type variable α captures the whole type of the argument, thus also its extra fields. Thanks to that the type system deduces for `(bump_counter(%{counter: 1, file: "foo.txt"})).file` the type string. The bounded polymorphic type above is encoded by set-theoretic types as follows (see [7]):⁶

```
14 $ (%{..., counter: integer()} and a -> %{..., counter: integer()} and a) when a: term()
```

for which Elixir provides the nifty shorthand `(a -> a) when a: %{..., counter: integer()}` of bounded polymorphism.

The example above may suggest that intersecting record types with type variables could play the same role as row polymorphism. Unfortunately, the example above is one of the few cases in which this works.⁷ This technique may work to type functions in which the input and the output have the same fields; but even in that case it is easy to have a partial loss of information. For instance, consider the following function that takes as input a record with a field `foo` and redefines its content (in Elixir, functions are annotated by the `$`-prefixed type that precedes their definition [8]):

```
15 $ (a, b) -> a when b: term(), a: %{..., foo: b}
16 def redefine_foo(x,y), do: %{x | foo: y}
```

Although we do not lose the static type information of any field of the argument (thanks to the type variable `a`), the type for the `:foo` field may lose precision. For example, the type deduced for `redefine_foo(%{foo: 42}, true).foo` is the union `integer() or boolean()`—rather than just `boolean()`—since the type variable `b` is unified with the *union* of the type of the second argument and the type of the field `foo`: of the first argument. Furthermore, this technique fails when we try to add a new field to a record or delete an existing field from it. For instance, consider again the function `Map.put`, whose use in line 4 can be abstracted as follows:

```
17 $ (%{...} and a -> %{..., domain: list(atom())} and a) when a: term()
18 def put_domain(x), do: Map.put(x, :domain, [:elixir])
```

⁶Intersections and unions have a precedence higher than arrows and records, and negation has the highest precedence of all.

⁷Even this is not true: it is just an approximation we did for presentation purposes, since it is unsound to deduce the type `a` for the result type. To see why, try to instantiate `a` with `%{counter: 42}`.

One might think that the use of the intersection with the type variable `a` captures all the fields of the argument, but the type declaration is wrong—and, as such, rejected by the type system—because if we instantiate the variable `a` by a type such as `%{domain: integer()}`, then we deduce for `put_domain` the type `%{domain: integer()} -> none()`, where `none()` is the empty type (resulting by simplifying the intersection in the codomain): this type states that the application of `put_domain` to an argument of type `%{domain: integer()}` must diverge (since any returned value must be in the empty type, which contains `none`), which is clearly wrong. A similar problem happens when we apply the record operations of deleting a field or of adding a field that is not already present.

The problem with the type in line 17 is that for each intersection in it not to be empty, the type variable `a` must be instantiated by a record type that contains all the fields of the input and of the output, in particular the field for `:domain`. If, as above, `:domain` has different types in the input and in the output, then one of the two intersections results empty (making the whole record type containing it to be empty) which, as explained above, is unsound. For the typing to work, we need the type variable to instantiate all the fields of the input *except the field for `:domain`*. This is exactly the role of row variables, which instantiate “all the other fields” of the record type. The function `put_domain` can be given any of the two following types (one for each line):

```
19 $ %{f} -> %{f, domain: list(atom())} when f: fields()
20 $ %{f, :domain => term()} -> %{f, domain: list(atom())} when f: fields()
```

The two types above are essentially two different syntaxes for the same type: the type in line 19 is syntactic sugar for the one in line 20, which, despite being more verbose, explicitly states in its input part, that the field `:domain` is either undefined or contains a value of any type. The type in line 20, thus, explicitly shows that the row variable `f` captures all fields except `:domain`.

Likewise, we need row variables for typing a function that deletes, say, the `:domain` field since, once again, the type of the deleted field will be different in the input and in the output:

```
21 $ %{f, :domain => term()} -> %{f, :domain => none()} when f: fields()
22 def del_domain(x), do: Map.delete(x, :domain)
```

The codomain of the type in line 21 states that the field for `:domain` must be absent (i.e., if present, it must contain a value of the empty type `none()`, of which there is none). As before, the type above can be more conveniently written as: `%{f} -> %{f, :domain => none()} when f: fields()`, and again, this works because `f` can only be instantiated to rows that do not contain a field for `:domain`.

Since we have established that we need row polymorphism, the next question is why not use the existing theory? A first reason for that is that to integrate row polymorphism in a semantic subtyping setting, we need to define subtyping for polymorphic records, and this requires to interpret the row-polymorphic record types as sets of values which, to our knowledge, was never done before. A second reason is the handling of optional fields, which, to the best of our knowledge, is unique to our setting and not addressed by other existing approaches (cf. the discussion on presence polymorphism in Section 4). A third quite challenging reason arises from the limitations of conventional unification techniques applied in row polymorphism; for instance, this issue becomes apparent when considering the following example:

```
23 type figure() = %{shape: "circle", perim: integer(), diam: float()} or
24               %{shape: "polygon", perim: integer(), edges: integer()}
25 $ {f, perim: integer()} -> {f, perim: float()} when f: fields()
26 def perim_to_float(x), do: %{x | perim: to_float(x.perim)}
```

The first two lines define the type of “figures”, which are records with an integer field `:perim` and with either a `:diam` or an `:edges` field, according to the value of their `:shape` field. In line 26 we define a function that transforms the integer field `:perim` of the input into float. Its type is given in line 25. Now, if we apply the function `perim_to_float` to an argument of type `figure()` we expect to deduce for it a type like `figure()` but where the `:perim` field is of type `float()`, that is

```
27 $ %{shape: "circle", perim: float(), diam: float()} or
28   %{shape: "polygon", perim: float(), edges: integer()}
```

but current theories of row polymorphism unify record types component-wise, which in our case would yield the following type which is less precise than (i.e., is a supertype of) the type above:

```
29 $ %{shape: "circle" or "polygon", perim: float(), :diam => float(), :edges => integer()}
```

where the `:shape` field has now a union type and `:diam` and `:edges` have become optional. To deduce the type in lines 27 and 28 the row variable `f` must be expanded into the union of two rows, one for the shape `circle` and the other for the shape `polygon`.

Even if the problem above can be solved by particular typing techniques, the presence of negation types in our theory invalidate such techniques in general (see example in [Appendix C.1](#)). Therefore, we need to develop an original technique to replace unification, so that it takes into account subtyping and enables substitutions to expand row variables into Boolean combinations of rows.

In conclusion, to embed row polymorphism in a type system featuring semantically defined union, intersection, and negation types, we need new theoretical developments to cope with the semantic interpretation of types and the inference of substitutions for type variables in the presence of subtyping and set-theoretic types.

1.3 Overview

In [Section 2](#) we define the syntax of types and the subtyping relation. We abandon Elixir’s syntax for maps/records and introduce in [Section 2.1](#) a more theoretically-oriented one: we denote records types as finite lists of field-type specifications of the form $\ell = \tau$, followed by a *tail* ζ specifying an infinite row of fields as in $\{\ell_1 = \tau_1, \dots, \ell_n = \tau_n \mid \zeta\}$. In this type, each ℓ_i denotes a label (or key) of a field, and labels are pairwise distinct; τ_i is either a type t or the union $t \vee \perp$, meaning that the field is optional with type t (i.e., Elixir’s `:key => t()` field) and absent if t is the empty type (i.e., `:key => none()`); ζ is either a row variable ρ , or “..” (meaning that the record type is open), or “ ϵ ” (meaning that the record is closed: its values contain all and only the fields specified in the type).

To define the subtyping relation on types, we give in [Section 2.2](#) an interpretation of types as sets of elements of a domain \mathcal{D} —whose elements, intuitively, represent the values of the language—and then define subtyping as containment of the interpretations. Following Frisch [20], records values are interpreted as quasi-constant functions, that is, functions that map all labels into \perp (meaning that the field for that label is undefined) except for a finite set of labels that are mapped into values. Therefore, (ground) record types are interpreted as sets of quasi-constant functions. More subtle is the interpretation for row variables which, as we saw, define the type of *all the labels except a few ones*; as a consequence our interpretation will map them into *partial* quasi-constant functions (as in [42]), requiring a careful handling of their domains. In [Section 2.3](#) we define an algorithm to decide the subtyping relation just defined. We do so by extending the subtyping algorithm of the monomorphic record types of CDuce [3]—on which we base our theory— to our polymorphic records. The resulting (backtrack-free) algorithm has the same order of complexity as the one for monomorphic record types, which is currently used in Elixir. Finally, we give a formal definition

for type substitutions in [Section 2.4](#), in particular for the case of row variables which are expanded into Boolean combinations of rows of fields, and prove that its application preserves subtyping.

In [Section 3](#) we define a language with operations on records. For those, several equivalent choices are possible [4]. We build records starting from the empty record value, noted $\{\}$, and adding new fields to it by the expression $\{e \text{ with } \ell = e'\}$ which extends the record (resulting from the evaluation of) e with the field $\ell = e'$, provided that a field for ℓ is not already present in e . The other operations on records are field selection, noted $e.\ell$, which returns the content of the field ℓ in e , and field deletion, noted $e \setminus \ell$ which removes from e the field labeled ℓ , if any. We define an operational semantics and a declarative type system, and we show that the latter is sound in the sense of Wright and Felleisen [49], by proving that every well-typed expression either diverges or returns a value of the expression's type ([Section 3.1](#)). Next, we define an algorithmic type system and prove it to be sound and complete with respect to the declarative one. The system is derived from the declarative one in a standard way: subsumption is embedded in the elimination rules, intersection introduction is essentially embedded in the typing of λ -abstractions, and the rule for applications performs instantiation and expansion by looking for a set of substitutions that make the type of the argument be a subtype of the domain of the function ([Section 3.2](#)).

[Section 3.3](#) studies the tallying problem, which plays the same role as the unification problem in type inference, but for a subtyping—rather than an equality—relation on types. The algorithmic system in [Section 3.2](#) is effective, provided that we produce an algorithm to deduce the type substitutions to apply to the types of the function and the argument when typing an application. Following Castagna et al. [10] this can be done by solving the tallying problem for our types, namely, the problem of deciding whether given two types, there exists a type substitution that makes one type subtype of the other. Castagna et al. [10] prove that the problem is decidable for a system with function and product type constructors and set-theoretic types, and give a sound and complete algorithm. However, defining a tallying algorithm for types with row variables is far more difficult. This is because substitutions replace row variables by Boolean combinations of rows of fields. We tackle this problem in [Section 3.3](#), where we define a tallying algorithm for row polymorphic types. We prove that the algorithm is sound but not complete, and we conjecture completeness for the case in which row variables are substituted by a single row of fields.

We conclude by discussing related work ([Section 4](#)) and further research directions ([Section 5](#)).

1.4 Contributions and Limitations

The overall contribution of this work is threefold, since it provides (i) a theory for a first-order polymorphic type system with row polymorphism and set-theoretic types, (ii) the practical motivations for such a system, as well as (iii) the relevant algorithms to apply it in practice. In particular, all the examples we presented in [Sections 1.1](#) and [1.2](#) are typed by our system.

The technical contributions can be summarized as follows:

- (1) We describe a first-order polymorphic type theory with union, intersection and negation type connectives, and function and record type constructors, where record types can be either closed, open, or specify a row variable, and their fields can be declared optional ([Section 2.1](#)). We define a subtyping relation for these types by providing an interpretation where types are interpreted as set of values and subtyping as set containment ([Section 2.2](#)).
- (2) We prove that the subtyping relation is decidable and provide a backtrack-free algorithm to decide it ([Section 2.3](#)) with the same order of complexity as the one implemented for Elixir [16].
- (3) We define type substitutions that map row variables into Boolean combinations of rows, and prove that the application of type substitutions preserves subtyping ([Section 2.4](#)).

- (4) We define a declarative type system for a record calculus with record extension, selection, and deletion and prove its soundness (Section 3.1).
- (5) We define an algorithmic system that we prove sound and complete with respect to the declarative one (Section 3.2).
- (6) We define an algorithm for the *tallying problem* for our system, that is, the problem of deciding whether given two types there exists a type substitution that make one subtype of the other; we prove soundness of the algorithm (Section 3.3).

The system defined here presents some limitations. Some are expected and characteristic of the kind of systems we consider here: the typing relation is not decidable (this is typical of systems with intersection types) and the type system has no principal types (which is already the case both for systems with polymorphic set-theoretic types [10, 11] and for expressive record type systems [4]). Other limitations are instead new, in particular that the tallying algorithm is sound but not complete (an example is given in Example 3.5; a complete algorithm exists when record types are kept out of the equation: see Castagna et al. [10]). We prove that one of the reasons for incompleteness is that we interpret row variables into Boolean combinations of rows rather than into single rows, and we conjecture that completeness can be recovered in the latter case, but at the expenses of the type system which can type fewer expressions (cf. Example C.2). Note however that all the examples given in the introduction fall outside the incompleteness area: as Example 3.5 shows, building an example for incompleteness requires the application of higher-order functions whose types map unions of record types into similar unions of record types.

From a practical point of view, the main limitation of this system is that it does not feature first class record labels, that is, the operations for field selection, extension, and deletion must specify nominal labels which, thus, cannot be obtained as the result of a computation. This important omission might hinder the application of our theory to dynamic languages where such a feature is widely used. This omission, however, is deliberate since we wanted to focus on the problem of row polymorphism, and having first-class labels is mostly orthogonal to it. We believe that it will not be hard to extend our work on the lines of Castagna [6] to add first class labels to our system, and we leave it for future work. Finally, we expect that implementing our system in a language such as Elixir will not affect the performance of the type checker: the complexity of our subtyping algorithm is the same as the one currently implemented in Elixir, while the complexity of the tallying algorithm and, thus, of type inference, is the same as the one implemented in CDuce [10] and planned for Elixir [8], up to a low multiplicative factor (cf. Footnote 13). Upcoming work on implementing the type system (in CDuce) shall provide empirical evidence.

2 Types

We introduce the syntax of types (Section 2.1) and their set-theoretic interpretation from which we derive the subtyping relation (Section 2.2). We define the algorithm to decide the subtyping relation (Section 2.3) and prove that subtyping is preserved by type and row substitutions (Section 2.4).

2.1 Syntax of Types

DEFINITION 2.1 (TYPES, ROWS AND KINDS). *Let \mathcal{L} be a countable set of labels ranged over by ℓ . The set \mathcal{T} of types (ranged over by t) contains all terms coinductively generated by the corresponding grammar below, and that (1) have a finite number of different sub-terms (regularity) and (2) in which every infinite branch contains an infinite number of occurrences of the record or arrow type constructors (contractivity). The set \mathcal{R} of rows (ranged over by r) as well as the set of field-types (ranged over by τ) contain all terms inductively generated by the corresponding grammars below.*

Kinds	κ	$::=$	$\star \mid \star_{\perp} \mid \text{Row}(L)$
Types	t	$::=$	$\alpha \mid b \mid t \rightarrow t \mid \{\ell = \tau, \dots, \ell = \tau \mid \zeta\} \mid t \vee t \mid \neg t \mid \mathbb{0}$
Field-types	τ	$::=$	$\theta \mid t \mid \perp \mid \tau \vee \tau \mid \neg \tau$
Tails	ζ	$::=$	$\rho \mid \epsilon \mid ..$
Rows	r	$::=$	$\langle \ell = \tau, \dots, \ell = \tau \mid \zeta \rangle^L \mid r \vee r \mid \neg r$

where, α, θ, ρ range, respectively, on type variables, field-type variables, and row variables; \perp is a distinguished symbol different from all types; and (from now on) $L \in \mathcal{P}_{\text{fin}}(\mathcal{L})$ is a finite set of labels.

Following a mathematical logic terminology, basic types, arrows, and records are called *type constructors* and yield *type atoms*, while unions, intersections, and negations are *type connectives*. Our system use kinds. Types are of kind \star , field-types of kind \star_{\perp} , and we have an infinite set of kinds for rows, parametrized by a finite set L : a row indexed by the set L is of kind $\text{Row}(L)$. We use T to range over types, field-types, and rows (i.e., T stands for either $t, \tau, \text{ or } r$), and define $T_1 \wedge T_2 \stackrel{\text{def}}{=} \neg(\neg T_1 \vee \neg T_2)$ and $T_1 \setminus T_2 \stackrel{\text{def}}{=} T_1 \wedge \neg T_2$. For every kind, besides the full set of type connectives, there are a bottom and a top element (forming a lattice w.r.t. subtyping). In \star , the top type is noted $\mathbb{1} \stackrel{\text{def}}{=} \neg \mathbb{0}$; in \star_{\perp} , the top field-type is $\mathbb{1} \vee \perp$ (notice that $\mathbb{1}$ contains all types, but not \perp which is not a type); in each kind $\text{Row}(L)$, the top row element is $\langle \text{I..} \rangle^L$. We use the generic notation $\mathbb{0} \stackrel{\text{def}}{=} \neg \langle \text{I..} \rangle^L$ for the bottom element in $\text{Row}(L)$, with L being, thus, implicitly given by the context.

Besides the aforementioned connectives, the types t of [Definition 2.1](#) are made of variables (from a countable set \mathcal{V}_t and ranged over by α), a finite set \mathcal{B} of basic types (e.g., Int, Bool ; ranged over by b), function types, and record types. Coinduction accounts for recursive types and comes with the usual restrictions of regularity —necessary for the decidability of the subtyping relation— and contractivity —which rules out meaningless types such as an infinite tower of negations, while providing a well-founded order for inductive proofs (see [7] for details). Notice that since both field-types and rows are built inductively, they are always *finite* unions or negations of, respectively, field-types or rows —this aligns with the contractivity requirement of types—, which are formed of (possibly infinite) types.

Records. Our records are based on the theory for records defined by Frisch [20] (see [6] for a description in English) and first used in CDuce. Our work extends the (monomorphic) record theory of [20] with row and field-type variables. In Frisch’s theory, a record *value* is a total function on \mathcal{L} that maps a finite set of labels into values, and all the remaining labels to a distinguished symbol \perp representing the undefined (such a function is dubbed *quasi-constant* by Frisch: cf. [Definition 2.2](#)).

Record type atoms (ranged over by R) are types of the form $\{\ell_1 = \tau_1, \dots, \ell_n = \tau_n \mid \zeta\}$, that is, an unordered list describing the mapping of a finite set of pairwise distinct labels into field-types, which is followed by a *tail* ζ that covers the infinitely many remaining labels. We often use the more compact notation $\{(\ell = \tau_{\ell})_{\ell \in L} \mid \zeta\}$, where $L \in \mathcal{P}_{\text{fin}}(\mathcal{L})$. For $R = \{(\ell = \tau_{\ell})_{\ell \in L} \mid \zeta\}$, we define $\text{lab}(R) \stackrel{\text{def}}{=} L$ and $\text{tail}(R) \stackrel{\text{def}}{=} \zeta$.

Fields. In [20], field-types τ are either: (a) *mandatory* when $\tau = t$ with type t ; or (b) *optional* when $\tau = t \vee \perp$ with type t , and in particular always undefined if $\tau = \perp$ —i.e., $\tau = \mathbb{0} \vee \perp$ (notice that undefined fields cannot be typed just by $\mathbb{0}$: records are modeled as (indexed) products, in which a single empty field makes the whole record empty; also notice that since \perp is distinct from all types, then $t \vee \perp \neq t$ and $\perp \wedge t = \emptyset$ for any type t). Our definition adds field-type variables (*field variables* for short), ranged over by θ and drawn from a countable set \mathcal{V}_f . In what follows, they are used in two ways: (1) to solve the tallying problem (see [Section 3.3](#)) and (2) to implement *presence polymorphism* without additional effort (see the discussion in [Section 4](#)). The introduction of field variables forces us to loosen the form of field-types by allowing arbitrary Boolean combinations.

Rows. The tail ζ of a record type atom $R = \{(\ell = \tau_\ell)_{\ell \in L} \mid \zeta\}$ can be of three sorts. If $\zeta = \epsilon$, then R is *closed*, and only includes records that assign \perp to every label outside L . If $\zeta = ..$, then R is *open*, and imposes no restriction on the values of the fields outside L . That is, those labels are given field-type $\mathbb{1} \vee \perp$. Giving $\mathbb{1}$ would be unsound, as it would imply that the selection of any remaining field of a record of this type would always be well-typed, even for fields not containing a value (such fields always exist as records are built inductively). New in our work with respect to [20] is that ζ may also be a row variable (taken from a countable set \mathcal{V}_r ranged over by ρ) in which case R is *polymorphic*.

In R , the row variable $\rho = \zeta$ defines the fields for the cofinite set of labels $\text{def}(\rho)$ that we call the *definition space* of ρ . Now, since record types are **total** functions on \mathcal{L} , we cannot use them to interpret row variables. For this, we use the new syntactic category of *rows* from Definition 2.1, that denote **partial** functions on \mathcal{L} defined on co-finite sets of labels.

Rows are of the form $\langle (\ell = \tau_\ell)_{\ell \in L} \mid \zeta \rangle^{L'}$. The relevant part is the set $L' \in \mathcal{P}_{\text{fin}}(\mathcal{L})$ at the index, which denotes the finite set of labels on which the row is *not* defined. In other terms, the row above is a total function from $\mathcal{L} \setminus L'$ into field-types: the τ_ℓ 's define the fields for the labels in L and the tail ζ the fields for the labels in $\mathcal{L} \setminus (L \cup L')$.

Of course, not every row or record type is well-formed, since we must ensure that the various L , L' , and $\text{def}(\rho)$ form a partition of \mathcal{L} . They have to verify the following three properties (enforced statically by a kinding system whose straightforward definition is given in Appendix A, Fig. 3):

- (1) In a type $\{(\ell = \tau_\ell)_{\ell \in L} \mid \rho\}$ we must have $\mathcal{L} \setminus L = \text{def}(\rho)$;
- (2) In a row $\langle (\ell = \tau_\ell)_{\ell \in L} \mid \zeta \rangle^{L'}$ we must have $L \cap L' = \emptyset$ and, if $\zeta = \rho$, then $\mathcal{L} \setminus (L \cup L') = \text{def}(\rho)$;
- (3) Unions (and, thus, intersections) are only on rows defined on the same set of labels.

Finally, for all $\ell \in \mathcal{L}$, we define $R(\ell)$ to yield the field-type associated to ℓ by R :

$$R(\ell) \stackrel{\text{def}}{=} \begin{cases} \tau_\ell & \text{if } \ell \in L; \text{ otherwise:} \\ \perp & \text{if } \zeta = \epsilon \\ \mathbb{1} \vee \perp & \text{if } \zeta = .. \text{ or } \zeta \in \mathcal{V}_r \end{cases}$$

This operator, as well as others, is trivially transferred from record types to rows. Notice that in the case of open and closed records (and rows), the choice of L for a record type is not canonical, as for instance $\{\ell_1 = \text{Int} \vee \perp, \ell_2 = \perp \mid \epsilon\}$ and $\{\ell_1 = \text{Int} \vee \perp \mid \epsilon\}$ are semantically equivalent. Since row variables have a constant definition space however, a record type like $\{\ell = \mathbb{1} \vee \perp \mid \rho\}$ has a single (top-level) representation with $L = \{\ell\} = \mathcal{L} \setminus \text{def}(\rho)$.

Example 2.1 (Examples of record types and rows). $t = \{\ell_1 = \text{Int}, \ell_2 = \text{Bool} \mid ..\}$ is an open record type, whose values are records with at least an integer in ℓ_1 and a boolean in ℓ_2 —e.g., $\{\ell_1 = 3, \ell_2 = \text{True}, \ell_3 = \text{'a'}\}$. Its closed counterpart, $\{\ell_1 = \text{Int}, \ell_2 = \text{Bool} \mid \epsilon\}$, types records in which both and only ℓ_1 and ℓ_2 have some value. The type t is equivalent to (i.e., it is both a subtype and a supertype of) both $\{\ell_1 = \text{Int}, \ell_2 = \text{Bool}, \ell_4 = \mathbb{1} \vee \perp \mid ..\}$ and $\{\ell_1 = \text{Int} \mid ..\} \wedge \{\ell_2 = \text{Bool} \mid ..\}$. By De Morgan's laws, $\neg t$ is equivalent to $\neg\{\ell_1 = \text{Int} \mid ..\} \vee \neg\{\ell_2 = \text{Bool} \mid ..\}$ and thus to $\{\ell_1 = \neg\text{Int} \vee \perp \mid ..\} \vee \{\ell_2 = \neg\text{Bool} \vee \perp \mid ..\}$. The type $\{\ell_1 = 0 \mid ..\}$ is equivalent to \emptyset , and so are both $\{\ell_2 = 0 \mid \epsilon\}$ and $\{\ell_1 = 0 \mid \rho\}$. \square

2.2 Subtyping Relation

The subtyping relation characterizes the type system: union and intersection types are the least upper bounds and greatest lower bounds of this relation, and the typing relation relies on subtyping to compare types. Our goal is to extend the monomorphic type theory of records of Frisch [20] to a polymorphic one, obtained by adding row variables. For this, we stick to the technique employed to extend the theory of semantic subtyping on monomorphic types to type-polymorphic ones [13, 22, 25]. This technique can be distilled into three conceptual steps:

- (1) *Define the subtyping relation on monomorphic types.* This is done in [22] by the definition of a *set-theoretic model*. This definition describes how to interpret types as subsets of some domain whose elements represent the values of the language. Given a specific model (i.e., a specific domain \mathcal{D} and an interpretation function $\llbracket \cdot \rrbracket$ from types in \mathcal{T} to sets in $\mathcal{P}(\mathcal{D})$), this induces a subtyping relation defined as the containment of the interpretations (i.e., $t \leq t' \stackrel{\text{def}}{=} \llbracket t \rrbracket \subseteq \llbracket t' \rrbracket$).
- (2) *Extend the definition of the model to polymorphic types.* This is done by making the interpretation of types parametric in the interpretation η of *type variables* as sets of values. Subtyping can then be defined as containment for every type variable interpretation η (i.e., $t \leq t' \stackrel{\text{def}}{=} \forall \eta. (\llbracket t \rrbracket \eta \subseteq \llbracket t' \rrbracket \eta)$), but only for models that satisfy a so-called “convexity” condition [13] (see after [Definition 2.3](#)).
- (3) *Exhibit a specific convex model for polymorphic types and deduce the subtyping relation.* Gesbert et al. [25] show that a convex model for polymorphic types can be obtained by taking a specific model for monomorphic types and indexing all its elements by finite sets of type variables.

Henceforth, we apply the same approach to record types:

- (r1) The subtyping relation for monomorphic record types is defined by interpreting them as sets of *record values* (i.e., **total** functions from labels to values).
- (r2) We extend this interpretation to polymorphic record types, by making it parametric in the interpretation η of *row variables* into sets of *rows* (i.e., **partial** functions from labels to values).
- (r3) We define a convex model of polymorphic record types, by taking a specific model for monomorphic record types and indexing all its elements by finite sets of *row variables*.

The sole distinction between the two approaches, thus, lies in the interpretation of *type variables* and of *row variables*. While *type variables* are mapped into sets of values, *row variables* are mapped into sets of *rows*. Rows are not values themselves but rather “chunks” of values: both (record) values and rows are quasi-constant functions; however, (record) values are total functions, whereas rows are partial ones. We thus achieve the same conceptual simplicity as the polymorphic extension of semantic subtyping, though the technical development is, in our case, far more involved.

For space reasons, we present here only the final result of this process, that is, the specific convex model of step (r3), given by the domain of [Definition 2.3](#) and the interpretation of [Definition 2.5](#). We then derive from it the definition of the subtyping relation ([Definition 2.6](#)) and a decision procedure that we prove sound, complete, and terminating ([Lemma 2.3](#) and [Proposition 2.4](#)). The development of the first two steps is necessary only to prove that the domain and the interpretation given below satisfy the properties of model and of convexity. This development and the corresponding proofs are given in [Appendix A.3](#). Although a detailed explanation of these properties is outside the scope of this presentation, we want to stress that without the model property the definition of subtyping would not be well-founded and without the convexity property the decision procedure would not be sound (see [13, 22] for details).

To interpret record values we follow Frisch [20], and represent each record value by a quasi-constant function that either maps labels into values (i.e., the elements of \mathcal{D}) or into \perp . Let us write \mathcal{D}_\perp for $\mathcal{D} \cup \{\perp\}$ where \perp is a distinguished element not in \mathcal{D} . Quasi-constant functions are total functions that map all but a finite set of elements of their domain into the same default value. Formally, we have the following definition.

DEFINITION 2.2 ([20]). *A function $r : \mathcal{L} \rightarrow \mathcal{D}_\perp$ is quasi-constant if the set $\{\ell \in \mathcal{L} \mid r(\ell) \neq \perp\}$ is finite. We use $\mathcal{L} \rightarrow \mathcal{D}_\perp$ to denote the set of quasi-constant functions from \mathcal{L} to \mathcal{D}_\perp and $\{\ell_1 = \delta_1, \dots, \ell_n = \delta_n, _ = \perp\}$ to denote the quasi-constant function $r : \mathcal{L} \rightarrow \mathcal{D}_\perp$ defined by $r(\ell_i) = \delta_i$ for $i = 1..n$ and $r(\ell) = \perp$ for $\ell \in \mathcal{L} \setminus \{\ell_1, \dots, \ell_n\}$.*

We also have to interpret rows, which are defined only on a cofinite subset of \mathcal{L} . In other terms, rows are *partial* quasi-constant functions from \mathcal{L} to \mathcal{D}_\perp , that we note $\mathcal{L} \dashv \rightarrow \mathcal{D}_\perp$. Since a total function is also a partial one, then we need just the latter in our domain to interpret record types and rows. This yields the following definition of domain.

DEFINITION 2.3 (DOMAIN). *The interpretation domain \mathcal{D} for types, is the set of finite terms d inductively produced by the following grammar, where c ranges over the set \mathcal{C} of constants, ℓ over the set \mathcal{L} of labels, and V over sets of variables contained in $\mathcal{V} = \mathcal{V}_t \cup \mathcal{V}_f \cup \mathcal{V}_r$. The interpretation domain \mathcal{D}_\perp for fields (resp. \mathcal{D}_{row} for rows) is the set of terms δ (resp. δ).*

$$\begin{aligned} d &::= c^V \mid \{(d, \partial), \dots, (d, \partial)\}^V \mid \text{Rec}(\delta)^V & \text{def}(\delta) &= \mathcal{L} \\ \delta &::= \langle \ell_1 = \delta, \dots, \ell_n = \delta, _ = \perp^0 \rangle_L^V & L &\in \mathcal{P}_{\text{fin}}(\mathcal{L} \setminus \{\ell_1, \dots, \ell_n\}) \\ \partial &::= d \mid \Omega \\ \delta &::= d \mid \perp^V \end{aligned}$$

We use D for an element that is either d , δ or δ . We define $\text{def}(\langle \ell = \delta_\ell \rangle_{L_2}^V) = \mathcal{L} \setminus L_2$. We use $\text{tag}(D)$ to denote the set of variables indexing D , that is, $\text{tag}(c^V) = \text{tag}(\{(d, \partial), \dots, (d, \partial)\}^V) = \text{tag}(\text{Rec}(\delta)^V) = \text{tag}(\langle \ell_1 = \delta, \dots, \ell_n = \delta, _ = \perp^0 \rangle_L^V) = \text{tag}(\perp^V) = V$.

The elements of the domain are constants \mathcal{C} to interpret basic types, sets of finite binary relations $\mathcal{P}_{\text{fin}}(\mathcal{D} \times \mathcal{D}_\Omega)$ to interpret function types, and *partial* quasi constant functions $\mathcal{L} \dashv \rightarrow \mathcal{D}_\perp$ to interpret rows (and record types by the total ones). The fact that functions are finite binary relations is a standard technique of semantic subtyping, and corresponds to interpreting function spaces into the infinite set of their finite approximations; that these binary relations can yield a distinguished element Ω (which, intuitively, represents a type error) is also a standard technique of semantic subtyping used to avoid $\mathbb{1} \rightarrow \mathbb{1}$ to be a supertype of all function types: since both aspects do not play any specific role in our work we will not further comment on them (see [22] for a detailed explanation or [6, Section 3.2] for a shorter one).

If we look more closely at the definition of the row elements in Definition 2.3, we see that they are *partial* quasi-constant functions in $\mathcal{L} \dashv \rightarrow \mathcal{D}_\perp$ with default value \perp . More precisely, the row element $\langle \ell_1 = \delta_1, \dots, \ell_n = \delta_n, _ = \perp^0 \rangle_L$ is the quasi-constant function $\{ \ell_1 = \delta_1, \dots, \ell_n = \delta_n, _ = \perp \}$ in $(\mathcal{L} \setminus L) \dashv \rightarrow \mathcal{D}_\perp$. When a row is total on \mathcal{L} , then it can be wrapped in a $\text{Rec}()$ constructor yielding (the interpretation of) a record value (the inverse operation is given in the Definition 2.4 below).

All these elements are indexed by a finite set of variables ranged over by V . This technique was introduced by Gesbert et al. [25] to interpret type variables (cf. Definition 2.5), while ensuring that the model we obtain is *convex* in the sense of Castagna and Xu [13]. Convexity is a property that prevents the definition of meaningless subtyping relations, by imposing that the interpretation of types changes uniformly for any possible change of the interpretation of the type variables.⁸ A sufficient condition to satisfy convexity is that the interpretation maps every type into an infinite set. Indexing each element of the domain with a finite set of variables is an easy way to guarantee this since, for instance, even the interpretation of the singleton type c is the infinite set $\{c^V \mid V \in \mathcal{P}_{\text{fin}}(\mathcal{V})\}$. In summary, the domain of Definition 2.3 is the one by Gesbert et al. [25], but where pairs (inhabiting product types) are replaced by record values of the form $\text{Rec}(\delta)$ and rows.

DEFINITION 2.4. *Let $R = \{(\ell = \tau_\ell)_{\ell \in L} \mid \zeta\}$. We define $\text{row}(R) = \langle (\ell = \tau_\ell)_{\ell \in L} \mid \zeta \rangle^0$. We extend this definition homomorphically to Boolean combinations of record type atoms.*

We have now all ingredients needed to define our set-theoretic interpretation for the types:

⁸Formally, convexity states that for every finite set of types, if for every interpretation of the type variables this sets contains at least one empty type, then it is because it contains a type that is empty for all interpretations.

DEFINITION 2.5 (INTERPRETATION). Let \mathcal{D} be the domain of [Definition 2.3](#) and \mathcal{T} the types of [Definition 2.1](#). We define a binary predicate $(D : T)$ (“the element D belongs to T ”) on $\mathcal{D} \times \mathcal{T} \cup \mathcal{D}_\perp \times \mathcal{T}_\perp \cup \mathcal{D}_{\text{row}} \times \mathcal{R}$ by induction on the pair (D, T) ordered lexicographically. The predicate is only defined if D is coherent with the kind of T : $D = d$ if $T = t$, $D = \delta$ if $T = \tau$, and $D = \mathfrak{d}$ if $T = r$ and $\text{dom}(D) = \text{def}(r)$.

Types:	$(d : \alpha) = \alpha \in \text{tag}(d)$	$(c^V : b) = c \in \mathbb{B}(b)$	$(\text{Rec}(\mathfrak{d})^V : R) = (\mathfrak{d} : \text{row}(R))$
	$(\{(d_1, \partial_1), \dots, (d_n, \partial_n)\}^V : t_1 \rightarrow t_2) = \forall i \in [1..n]. \text{ if } (d_i : t_1) \text{ then } (\partial_i : t_2)$		
Fields:	$(\delta : \theta) = \theta \in \text{tag}(\delta)$	$(\perp^V : \perp) = \text{true}$	
Rows:	$(\langle (\ell = \delta_\ell)_{\ell \in L_1, -} = \perp^0 \rangle_{L_2}^V : r) = (\forall \ell \in L_1. (\delta_\ell : r(\ell)))$		
			(1)
	and $(\forall \ell \in \text{def}(r) \setminus L_1. (\perp^0 : r(\ell)))$		
	and $\text{tail}(r) = \rho \implies \rho \in V$		
All:	$(D : T_1 \vee T_2) = (D : T_1) \text{ or } (D : T_2)$	<i>if T_1, T_2 of the same kind</i>	
	$(D : \neg T) = \text{not } (D : T)$	<i>if the kinds of D and T correspond</i>	
	$(D : T) = \text{false}$	<i>otherwise</i>	

We define the interpretation $\llbracket \cdot \rrbracket : \mathcal{T} \rightarrow \mathcal{P}(\mathcal{D})$ as $\llbracket t \rrbracket = \{d \in \mathcal{D} \mid (d : t)\}$.

We cannot define $\llbracket \cdot \rrbracket$ by induction on types, since their coinductive definition would make the definition ill-founded. Thus, [Definition 2.5](#) uses the predicate $(D : T)$ for which an inductive definition is possible thanks to the inductive definition of \mathcal{D} . The interpretation of types in [Definition 2.5](#) is mostly the same as in [\[25\]](#): a type variable α is interpreted as the set of all elements tagged by α ; a type $t_1 \rightarrow t_2$ is the set all the finite approximations of functions that map inputs of type t_1 into results of type t_2 ; and union, intersection, and negation types are mapped into the corresponding set-theoretic counterparts. The main difference with [\[25\]](#) is the interpretation of rows and, thus, of record types. Equation (1) defines when a row element is in the interpretation of a row r : it requires that all the components of the row element are in the interpretations of the types specified by r (first two lines), and if the tail of r is a row variable, then it must index the row element (last line).

DEFINITION 2.6 (SUBTYPING). Let $\llbracket \cdot \rrbracket : \mathcal{T} \rightarrow \mathcal{P}(\mathcal{D})$ be the interpretation from [Definition 2.5](#). It induces the following subtype relation in $\mathcal{T} \times \mathcal{T}$:

$$t_1 \leq t_2 \stackrel{\text{def}}{\iff} \llbracket t_1 \rrbracket \subseteq \llbracket t_2 \rrbracket$$

The interpretation also induces the subfield relation in $\mathcal{T}_\perp \times \mathcal{T}_\perp$ and subrow relation in $\mathcal{R} \times \mathcal{R}$ defined as

$$\tau_1 \leq \tau_2 \stackrel{\text{def}}{\iff} \llbracket \tau_1 \rrbracket^{\text{fld}} \subseteq \llbracket \tau_2 \rrbracket^{\text{fld}} \quad r_1 \leq r_2 \stackrel{\text{def}}{\iff} \llbracket r_1 \rrbracket^{\text{row}} \subseteq \llbracket r_2 \rrbracket^{\text{row}}$$

where, the interpretation $\llbracket \cdot \rrbracket^{\text{fld}} : \mathcal{T}_\perp \rightarrow \mathcal{P}(\mathcal{D}_\perp)$ is defined as $\llbracket \tau \rrbracket^{\text{fld}} = \{\delta \in \mathcal{D}_\perp \mid (\delta : \tau)\}$, and the interpretation $\llbracket \cdot \rrbracket^{\text{row}} : \mathcal{R} \rightarrow \mathcal{P}(\mathcal{D}_{\text{row}})$ is defined as $\llbracket r \rrbracket^{\text{row}} = \{\mathfrak{d} \in \mathcal{D}_{\text{row}} \mid (\mathfrak{d} : r)\}$.

2.3 Deciding Subtyping

Now that subtyping is defined, we need an effective decision procedure sound and complete with respect to this definition. Deciding subtyping amounts to deciding the emptiness of a type, since $t_1 \leq t_2$ is equivalent to $t_1 \wedge \neg t_2 \leq \emptyset$. From [\[22\]](#), we know that any type can be equivalently rewritten into a disjunctive normal form (DNF) of the form $\bigvee_{i \in I} (\bigwedge_{a \in P_i} a \wedge \bigwedge_{a \in N_i} \neg a \wedge \bigwedge_{\alpha \in V_i^p} \alpha \wedge \bigwedge_{\alpha \in V_i^n} \neg \alpha)$ where each intersection contains only atoms a 's with the same type constructors: they are all basic types, or all arrows, or all records. Thus, checking emptiness of a type amounts to checking emptiness of all these intersections.

We suppose the sets V_i^p and V_i^n to be disjoint, as otherwise the i -th intersection is trivially empty and can be discarded. Then, emptiness of the intersections cannot depend on the type variables whose intersection is not empty. Thus, we just need decision procedures for the emptiness of the

$\bigwedge_{a \in P_i} a \wedge \bigwedge_{a \in N_i} \neg a$ parts. Those are already known for every intersection of atoms, except for polymorphic records. What is still missing is a formula that characterizes the emptiness of an intersection of the form $\bigwedge_{R \in P} R \wedge \bigwedge_{R \in N} \neg R$, that is, that decides whether $\bigwedge_{R \in P} R \leq \bigvee_{R \in N} R$ holds.

To rephrase, given any type t , the subtyping procedure recursively apply these two steps:

- (1) Reduce t to a DNF $\bigvee_{i \in I} t_i$ with $t_i = \bigwedge_{a \in P_i} a \wedge \bigwedge_{a \in N_i} \neg a \wedge \bigwedge_{\alpha \in V_i^p} \alpha \wedge \bigwedge_{\alpha \in V_i^n} \neg \alpha$;
- (2) Check the emptiness of each t_i by checking if $\bigwedge_{a \in P_i} a \leq \bigvee_{a \in N_i} a$ is empty:
 - If the atoms are not records, we use the existing corresponding functions given in [20].
 - If they are (polymorphic) records, we use the new algorithm that we describe below.

Subtyping algorithm. Let $t = \bigwedge_{R \in P} R \wedge \bigwedge_{R \in N} \neg R$. Deciding emptiness of this type is done in two main steps. First, preprocess t by normalizing the positive side of the type to *isolate* row variables. For this, we use the equivalence between $\{(\ell = \tau_\ell)_{\ell \in L} \mid \zeta\}$ and $\{(\ell = \tau_\ell)_{\ell \in L} \mid ..\} \wedge \{(\ell = \mathbb{1} \vee \perp)_{\ell \in L} \mid \zeta\}$. Note that a type $\{(\ell = \mathbb{1} \vee \perp)_{\ell \in L} \mid \zeta\}$ will be abbreviated as $\{L \mid \zeta\}$. Second, apply the function Φ , the core of our algorithm that we describe below.

Let $L = \bigcup_{r \in P \cup N} \text{lab}(r)$ be the set of labels appearing explicitly in every (top-level) record atom of t . Our starting type t is equivalent to the following intermediate one:

$$\{(\ell = \bigwedge_{R \in P} R(\ell))_{\ell \in L} \mid ..\} \wedge \bigwedge_{R \in P} \{\text{lab}(R) \mid \text{tail}(R)\} \wedge \bigwedge_{R \in N} \neg R \quad (2)$$

This type was obtained by transforming the positive $\bigwedge_{R \in P} R$ part of t : we merged the fields over L into a single atomic record type, and grouped the tails of positive records in a separate intersection. Next, we are going to rewrite the type in (2) by splitting the middle intersection $\bigwedge_{R \in P} \{\text{lab}(R) \mid \text{tail}(R)\}$ in two: an intersection with all the record atoms whose tail is a row variable, and all the others that we will merge with the leftmost record in (2). For that, let us define ζ_\circ to represent the intersection of the tails of the records in P whenever this tail is either ϵ or $..$, that is, $\zeta_\circ = \epsilon$ if there is $R \in P$ such that $\text{tail}(R) = \epsilon$, and $\zeta_\circ = ..$ otherwise. If we take all the records in $\bigwedge_{R \in P} \{\text{lab}(R) \mid \text{tail}(R)\}$ whose tail is not a row variable and intersect them with the leftmost record in (2), then we obtain the record type $R_\circ = \{(\ell = \bigwedge_{R \in P} R(\ell))_{\ell \in L} \mid \zeta_\circ\}$. Notice that R_\circ is a monomorphic record type. For the remaining records in the middle intersection, let us denote by $V_p = \{\rho \mid \exists R \in P. \text{tail}(R) = \rho\}$ the set of all top-level type variables occurring in P . The intersection of atoms in (2) is then equivalent to the following type, which is the one for which we have to decide emptiness:

$$R_\circ \wedge \bigwedge_{\rho \in V_p} \{\mathcal{L} \setminus \text{def}(\rho) \mid \rho\} \wedge \bigwedge_{R \in N} \neg R \quad (3)$$

The second step of our algorithm is realized by the function $\Phi(R_\circ, V_p, N)$, where $R_\circ \not\leq \emptyset$:

$$\begin{aligned} \Phi(R_\circ, V_p, \emptyset) &:= \text{false} \\ \Phi(R_\circ, V_p, N \cup \{R\}) &:= \text{if } (\text{tail}(R) = .. \text{ or } \text{tail}(R) = \text{tail}(R_\circ) \text{ or } \text{tail}(R) \in V_p) \text{ then} \\ &\quad \forall \ell \in \text{lab}(R_\circ). (R_\circ(\ell) \leq R(\ell) \text{ or } \Phi(R_\circ \wedge \{\ell : \neg R(\ell) \mid ..\}, V_p, N)) \\ &\quad \text{else } \Phi(R_\circ, V_p, N) \end{aligned}$$

The function must decide whether $R_\circ \wedge \bigwedge_{\rho \in V_p} \{\mathcal{L} \setminus \text{def}(\rho) \mid \rho\} \leq \bigvee_{R \in N} R$, so it picks an $R \in N$ and generates the conditions to test the containment. The first clause of the definition states that if we already examined all $R \in N$, then subtyping does not hold, since $R_\circ \not\leq \emptyset$ and so its intersection with some row variables is also non-empty. If R_\circ is open and R is closed, or if R is polymorphic, but its row variable is not one in V_p , then the containment cannot come from this particular R , and it is discarded: this corresponds to the else branch of second clause. Otherwise, we are in the case in which either R_\circ is closed, or we are comparing two records types with a common row variable, or R is open. In these cases we compare R_\circ and R component-wise, and for each ℓ we check that either $R_\circ(\ell) \leq R(\ell)$ or that the part that is in excess in $R_\circ(\ell)$ is contained in the records remaining in N .⁹

⁹This formula generalizes the decomposition for tuples: e.g., if $t_\circ \times t'_\circ \not\leq \emptyset$ then $t_\circ \times t'_\circ \leq t_1 \times t'_1 \vee t_2 \times t'_2 \iff (t_\circ \leq t_1 \text{ or } (t_\circ \setminus t_1) \times t'_1 \leq t_2 \times t'_2)$ and $(t'_\circ \leq t'_1 \text{ or } t_1 \times (t'_\circ \setminus t'_1) \leq t_2 \times t'_2)$: see [6, Appendix D] for a longer explanation.

Example 2.2 (Subtyping). Consider the verification of the following subtyping relation:

$$\{a = \text{True}, b = \text{Int} \vee \text{Bool} \mid \rho\} \wedge \{b = \text{Int} \vee \text{String}, c = \text{Int} \mid \dots\} \leq \{a = \text{Bool}, b = \text{Int} \mid \rho\} \vee \{a = \text{Int} \mid \rho'\}$$

The first step of the subtyping algorithm isolates ρ , reducing the relation by equivalence into:

$$\{a = \text{True}, b = \text{Int}, c = \text{Int} \mid \dots\} \wedge \{a, b \mid \rho\} \wedge \neg\{a = \text{Bool}, b = \text{Int} \mid \rho\} \wedge \neg\{a = \text{Int} \mid \rho'\} \leq \emptyset$$

Following the notation used in equation (3), we have $R_o = \{a = \text{True}, b = \text{Int}, c = \text{Int} \mid \dots\}$, $V_p = \{\rho\}$ and $N = \{\{a = \text{Bool}, b = \text{Int} \mid \rho\}, \{a = \text{Int} \mid \rho'\}\}$. The function $\Phi(R_o, V_p, N)$ verifies subtyping in three steps. In the first step, it selects $\{a = \text{Int} \mid \rho'\}$ from N , which is discarded (i.e., in the second clause for Φ , the else branch is taken), since $\rho' \notin V_p$. Second, it selects $\{a = \text{Bool}, b = \text{Int} \mid \rho\}$ from N . Since $\rho \in V_p$, it finishes by checking every label a, b and c w.r.t. R_o (i.e., the then branch in Φ). Here, it successfully concludes for each of them, by directly checking the subtyping. \square

The function presented generalizes the version for monomorphic records given in [6] and currently used in Elixir. Interestingly, the sole difference is the addition of the test $(\text{tail}(R) \in V_p)$. Since V_p is constant in the function, then the complexity of this function and of its monomorphic version are the same.

LEMMA 2.3 (SOUNDNESS AND COMPLETENESS OF Φ). *Let R_o be a monomorphic record type, $V_p \subset \mathcal{V}$, finite and N a finite set of (polymorphic) atomic record types. Then,*

$$R_o \wedge \bigwedge_{\rho \in V_p} \{\mathcal{L} \setminus \text{def}(\rho) \mid \rho\} \leq \bigvee_{R \in N} R \iff R_o \leq \emptyset \text{ or } \Phi(R_o, V_p, N).$$

PROPOSITION 2.4. *The subtyping algorithm terminates. As a corollary, subtyping is decidable.*

2.4 Substitutions

The upcoming descriptions of the type system and of the inference algorithm rely on type, row, and field substitutions.

DEFINITION 2.7. *Substitutions, ranged over by σ , are total mappings from variables of kind κ to terms of kind κ (i.e., type variables to types, field variables to field-types, and row variables of definition space L to rows of definition space L) that are the identity everywhere except on a finite set of variables. This set is called the domain of the substitution σ and is defined as $\text{dom}(\sigma) = \{\alpha \mid \sigma(\alpha) \neq \alpha\} \cup \{\theta \mid \sigma(\theta) \neq \theta\} \cup \{\rho \mid \sigma(\rho) \neq \langle \mid \rho \rangle^{\mathcal{L} \setminus \text{def}(\rho)}\}$.*

The application of a substitution σ to a term T is denoted by $T\sigma$. Notice that the application is defined both on field-types and on rows, the latter being useful only for tallying. The application of a substitution must satisfy the following equalities.

$$\begin{array}{llll} \alpha\sigma = \sigma(\alpha) & b\sigma = b & \emptyset\sigma = \emptyset & (t_1 \rightarrow t_2)\sigma = t_1\sigma \rightarrow t_2\sigma \\ \theta\sigma = \sigma(\theta) & \perp\sigma = \perp & (\neg T)\sigma = \neg(T\sigma) & (T_1 \vee T_2)\sigma = T_1\sigma \vee T_2\sigma \end{array}$$

$$\{(\ell = \tau_\ell)_{\ell \in L} \mid \zeta\}\sigma = \begin{cases} \{(\ell = \tau_\ell\sigma)_{\ell \in L} \mid \sigma(\rho)\}, & \text{if } \zeta = \rho \\ \{(\ell = \tau_\ell\sigma)_{\ell \in L} \mid \zeta\}, & \text{otherwise.} \end{cases} \quad (4)$$

Where $\{(\ell = \tau_\ell)_{\ell \in L} \mid r\} \stackrel{\text{def}}{=} \{(\ell = \tau_\ell)_{\ell \in L} \mid \dots\} \wedge \{L \mid r\}$ and:
 $\{L \mid \langle (\ell = \tau_\ell)_{\ell \in L'} \mid \zeta \rangle^L\} \stackrel{\text{def}}{=} \{L, (\ell = \tau_\ell)_{\ell \in L'} \mid \zeta\} \quad \{L \mid r_1 \vee r_2\} \stackrel{\text{def}}{=} \{L \mid r_1\} \vee \{L \mid r_2\} \quad \{L \mid \neg r\} \stackrel{\text{def}}{=} \neg\{L \mid r\}$

The equalities above are standard, apart from the one in (4) which needs a definition for the notation $\{(\ell = \tau_\ell\sigma)_{\ell \in L} \mid \sigma(\rho)\}$, since $\sigma(\rho)$ is a row rather than a tail. The definition is given right after (4) and simply states that $\{(\ell = \tau_\ell\sigma)_{\ell \in L} \mid \sigma(\rho)\}$ stands for the record type obtained by recursively decomposing the Boolean combinations of the rows in $\sigma(\rho)$, until we arrive at single rows that are expanded in the record type (recall that rows are inductively defined). Substitution for rows is defined in the same way as for records (it suffices to change the delimiting brackets).

$$\begin{array}{c}
\text{(CONST)} \frac{}{\Delta \mid \Gamma \vdash_{\mathcal{D}} c : \mathbf{b}(c)} \qquad \text{(VAR)} \frac{}{\Delta \mid \Gamma \vdash_{\mathcal{D}} x : \Gamma(x)} \quad x \in \text{dom}(\Gamma) \\
\text{(ABS)} \frac{(\Delta \cup \Delta' \mid \Gamma, x : t_i \vdash_{\mathcal{D}} e : t'_i)_{i \in I}}{\Delta \mid \Gamma \vdash_{\mathcal{D}} \lambda^{\wedge_{i \in I}(t_i \rightarrow t'_i)} x.e : \wedge_{i \in I}(t_i \rightarrow t'_i)} \quad \Delta' = \text{vars}(\wedge_{i \in I} t_i \rightarrow t'_i) \\
\text{(APP)} \frac{\Delta \mid \Gamma \vdash_{\mathcal{D}} e_1 : t_1 \rightarrow t_2 \quad \Delta \mid \Gamma \vdash_{\mathcal{D}} e_2 : t_1}{\Delta \mid \Gamma \vdash_{\mathcal{D}} e_1 e_2 : t_2} \qquad \text{(EMP)} \frac{}{\Delta \mid \Gamma \vdash_{\mathcal{D}} \{\} : \{\mid \epsilon\}} \\

\text{(SEL)} \frac{\Delta \mid \Gamma \vdash_{\mathcal{D}} e : \{\ell = t \mid \dots\}}{\Delta \mid \Gamma \vdash_{\mathcal{D}} e.\ell : t} \qquad \text{(INTER)} \frac{\Delta \mid \Gamma \vdash_{\mathcal{D}} e : t_1 \quad \Delta \mid \Gamma \vdash_{\mathcal{D}} e : t_2}{\Delta \mid \Gamma \vdash_{\mathcal{D}} e : t_1 \wedge t_2} \\
\text{(SUB)} \frac{\Delta \mid \Gamma \vdash_{\mathcal{D}} e : t' \leq t}{\Delta \mid \Gamma \vdash_{\mathcal{D}} e : t} \qquad \text{(INST)} \frac{\Delta \mid \Gamma \vdash_{\mathcal{D}} e : t}{\Delta \mid \Gamma \vdash_{\mathcal{D}} e : t\sigma} \quad \text{dom}(\sigma) \cap \Delta = \emptyset
\end{array}$$

Fig. 1. Declarative type system

As expected, if $\text{dom}(\sigma) = \emptyset$, then $T\sigma = T$. If $\sigma(\rho) \leq \emptyset$ and $\text{tail}(\mathbf{R}) = \rho$, then $\mathbf{R}\sigma \leq \emptyset$. Thanks to the parametric interpretation of types, substitution preserves subtyping:

PROPOSITION 2.5. *If $t_1 \leq t_2$, then $t_1\sigma \leq t_2\sigma$ for any row substitution σ .*

3 Language

We define the syntax, static and dynamic semantics of a record calculus that we prove to be type sound (Section 3.1) and define a sound and complete typing algorithm for it (Section 3.2).

3.1 Syntax and Semantics

Expressions	$e ::= c \mid x \mid ee \mid \lambda^{\wedge_{i \in I}(t_i \rightarrow t'_i)} x.e \mid \{\} \mid \{e \text{ with } \ell = e\} \mid e.\ell \mid e \setminus \ell$
Values	$v ::= c \mid \lambda^{\wedge_{i \in I}(t_i \rightarrow t'_i)} x.e \mid \{\} \mid \{v \text{ with } \ell = v\}$
Evaluation contexts	$E ::= [] \mid Ee \mid vE \mid \{e \text{ with } \ell = E\} \mid \{E \text{ with } \ell = v\} \mid E.\ell \mid E \setminus \ell$

The syntax above describes a functional language with constants, functions, and records with field selection ($e.\ell$), addition ($\{e \text{ with } \ell = e\}$), and deletion ($e \setminus \ell$). As customary in semantic subtyping, λ -abstractions are annotated by their type, which is an intersection of arrow types. We use $\{\ell_1 = e_1, \dots, \ell_n = e_n\}$ as syntactic sugar for $\{\dots \{\} \text{ with } \ell_1 = e_1\} \dots \text{ with } \ell_n = e_n\}$.

The semantics of the language is given by the call-by-value weak reduction defined below:

$[R_{\text{app}}]$	$(\lambda^t x.e)v \rightsquigarrow e[v/x]$
$[R_{\text{sel}}^-]$	$\{v \text{ with } \ell = v'\}.\ell \rightsquigarrow v'$
$[R_{\text{sel}}^{\neq}]$	$\{v \text{ with } \ell' = v'\}.\ell \rightsquigarrow v.\ell$ if $\ell \neq \ell'$
$[R_{\text{del}}^-]$	$\{v \text{ with } \ell = v'\} \setminus \ell \rightsquigarrow v \setminus \ell$
$[R_{\text{del}}^{\neq}]$	$\{v \text{ with } \ell' = v'\} \setminus \ell \rightsquigarrow \{v \setminus \ell \text{ with } \ell' = v'\}$ if $\ell \neq \ell'$
$[R_{\text{emp}}]$	$\{\} \setminus \ell \rightsquigarrow \{\}$
$[R_{\text{ctx}}]$	$E[e] \rightsquigarrow E[e']$ if $e \rightsquigarrow e'$

where $e[v/x]$ is the term obtained by standard capture-avoiding substitution of v for x in e , defined modulo α -equivalence. Notice that the deletion of a label ℓ is defined for the empty record $\{\}$ but selection is not: selection requires the presence of the field ℓ while deletion does not.

The terms of the language are typed by the declarative type system in Fig. 1, whose judgments have the form $\Delta \mid \Gamma \vdash_{\mathcal{D}} e : t$, where $\Delta \subseteq \mathcal{P}_{\text{fin}}(\mathcal{V}_t \cup \mathcal{V}_f \cup \mathcal{V}_r)$ is a set of monomorphic variables (i.e., variables that cannot be instantiated) and Γ a type environment from expression variables to types.

The rules for the functional part are inspired from those by Castagna et al. [11]. Constants are typed by a given function \mathbf{b} which maps each constant to its basic type (CONST).¹⁰ Rule (ABS) checks that a function has all the types declared in its annotation: for each $t_i \rightarrow t'_i$, it checks that the body e is of type t'_i under the environment in which x is given type t_i and the set Δ' of *all* the variables in the annotation is added to the set of monomorphic variables (vars(t) returns the set of type, field, and row variables in t : cf. Definition B.2). The rules for intersection introduction (INTER) and subsumption (SUB) are the usual ones: if an expression e has two types, then it also has their intersection; if an expression e has type t' , then it also has any supertype of t (we use the notation $\Delta \mid \Gamma \vdash_{\mathcal{D}} e : t' \leq t$ in the premises of a rule, to indicate that the rule has premise $\Delta \mid \Gamma \vdash_{\mathcal{D}} e : t$ and side condition $t' \leq t$). The instantiation rule (INST), can instantiate any type variable unless it is in the set of monomorphic variables Δ , as this would be unsound.

The new rules of this system are those for record expressions and their operations. The empty record value has the closed empty record type: (EMP). Rule (SEL) states that selection is typable only if the selected field is present, in which case its type is given to the select expression. Rule (EXT) types a strict extension of an expression e of type t by the expression e' on label ℓ , only if the field ℓ is undefined in e , that is, the type of e is a subtype of $\{\ell = \perp \mid \dots\}$. Rule (DEL) states that we can delete a field ℓ from an expression e provided that it is record (i.e., its type is a subtype of $\{\dots\}$).

The types of the expressions typed by (EXT) and (DEL) are both obtained in similar ways. First, we compute the operator $t \setminus \ell$ —whose formal definition we give below— which returns $\text{row}(t)$ truncated by the field of label ℓ . Then, we put back the field of label ℓ with the desired field-type (t' or \perp) using the operation $\{(\ell = \tau_{\ell})_{\ell \in L} \mid r\}$ we defined in Section 2.4 for substitutions (cf. Eq. (4)).

We define the operator $t \setminus \ell$, on DNFs: let $t = \bigvee_{i \in I} \bigwedge_{R \in P_i} R \wedge \bigwedge_{R \in N_i} \neg R \wedge \bigwedge_{\alpha \in V_i} \alpha \wedge \bigwedge_{\alpha \in V_n} \neg \alpha$. Then, $t \setminus \ell \stackrel{\text{def}}{=} \bigvee_{i \in I} \bigwedge_{R \in P_i} R \setminus \ell \wedge \bigwedge_{R \in N_i} (\neg R) \setminus \ell$ where for the literals R and $\neg R$ the definition is:

$$\begin{aligned} \{(\ell' = \tau_{\ell'})_{\ell' \in L} \mid \zeta\} \setminus \ell &= \begin{cases} \{(\ell' = \tau_{\ell'})_{\ell' \in L \setminus \{\ell\}} \mid \zeta\}^{\{\ell\}} & \text{if } \ell \in L \text{ or } \zeta \notin \mathcal{V}_r \\ \{(\ell' = \tau_{\ell'})_{\ell' \in L} \mid \dots\}^{\{\ell\}} & \text{otherwise} \end{cases} \\ (\neg\{(\ell' = \tau_{\ell'})_{\ell' \in L} \mid \zeta\}) \setminus \ell &= \begin{cases} \neg\{(\ell' = \tau_{\ell'})_{\ell' \in L \setminus \{\ell\}} \mid \zeta\}^{\{\ell\}} & \text{if } (\ell \in L \text{ and } \tau_{\ell} = \perp \vee \perp) \text{ or } (\ell \notin L \text{ and } \zeta = \dots) \\ \{(\dots)\}^{\{\ell\}} & \text{otherwise} \end{cases} \end{aligned}$$

First, notice that the type variables in the DNF are simply erased. This is not restrictive in practice, as intersections with top-level type variables are used only to implement bounded polymorphism which, as argued in the introduction, cannot be used for extensions and deletions, these requiring instead the use of row variables. The definition for the positive literal R consists of two cases. The first case is the intuitive one, with no interference from a negation or a row variable: the row is undefined on ℓ , so we remove the field for ℓ (if any) and index the row by $\{\ell\}$. In the second case, R is polymorphic and ℓ is in the definition space of its tail; therefore, similarly to what we do for type variables, we subsume R to an open record before deleting ℓ . For instance, if $x : \{a = \text{Int} \mid \rho\}$, then the type deduced for $x \setminus b$ is $\{a = \text{Int}, b = \perp \mid \dots\}$: the information bound to ρ must be forgotten since b is in definition space of ρ .¹¹

¹⁰The functions \mathbf{b} and \mathbb{B} used in Definition 2.5 must satisfy $c \in \mathbb{B}(\mathbf{b}(c))$ for all $c \in C$.

¹¹We can avoid this in practice. For instance, we can give to `def add_delete(x), do: Map.delete(%{x | a: x.a + 1}, :b)` the type: `%{f, a: integer()} -> %{f, a: integer(), :b => none()} when f: fields()`, where `f` plays the same role as ρ in the types above. Here we do not need to replace the second occurrence of `f` by “...” since, as we explained for the code in lines 19 and 20, we enforce in practice that this type stands for `%{f, a: integer(), :b => term()} -> %{f, a: integer(), :b => none()} when f: fields()` and, thus, `:b` is not in the definition space of `f`.

$$\begin{array}{c}
\text{(ABS)} \frac{(\Delta \cup \Delta' \mid \Gamma, x : t_i \vdash_{\mathcal{A}} e : t_i'' \sqsubseteq_{\Delta \cup \Delta'} t_i')_{i \in I}}{\Delta \mid \Gamma \vdash_{\mathcal{A}} \lambda^{\wedge_{i \in I} (t_i \rightarrow t_i')} x.e : \wedge_{i \in I} (t_i \rightarrow t_i')} \Delta' = \text{vars}(\wedge_{i \in I} t_i \rightarrow t_i') \\
\text{(APP)} \frac{\Delta \mid \Gamma \vdash_{\mathcal{A}} e_1 : t_1 \quad \Delta \mid \Gamma \vdash_{\mathcal{A}} e_2 : t_2}{\Delta \mid \Gamma \vdash_{\mathcal{A}} e_1 e_2 : t} t \in t_1 \bullet_{\Delta} t_2 \quad \text{(DEL)} \frac{\Delta \mid \Gamma \vdash_{\mathcal{A}} e : t}{\Delta \mid \Gamma \vdash_{\mathcal{A}} e \setminus \ell : \{\ell = \perp \mid r\}} r \in t \odot_{\Delta} \ell \\
\text{(SEL)} \frac{\Delta \mid \Gamma \vdash_{\mathcal{A}} e : t}{\Delta \mid \Gamma \vdash_{\mathcal{A}} e.\ell : t_{\ell}} t_{\ell} \in \Pi_{\Delta}^{\ell}(t) \quad \text{(EXT)} \frac{\Delta \mid \Gamma \vdash_{\mathcal{A}} e : t \quad \Delta \mid \Gamma \vdash_{\mathcal{A}} e' : t'}{\Delta \mid \Gamma \vdash_{\mathcal{A}} \{e \text{ with } \ell = e'\} : \{\ell = t' \mid r\}} r \in t \odot_{\Delta}^{\perp} \ell
\end{array}$$

Fig. 2. Algorithmic type system (plus (CONST), (VAR), (EMP), which are as in Fig. 1)

Next consider the case of a negative atom $\neg R$. First, suppose $R(\ell) \neq \perp \vee \perp$ (i.e., either $\ell \in L$ and $\tau_{\ell} \neq \perp \vee \perp$ or $\ell \notin L$ and $\zeta = \epsilon$). Then, the type $\neg R$ contains, among others, all row elements such that the field ℓ is not of type $R(\ell)$ (since $R(\ell) \neq \perp \vee \perp$, then there exists at least one such element), and every other field is of arbitrary value. Hence, the set obtained from removing the field ℓ from these values gives all quasi-constant functions on $\mathcal{L} \setminus \{\ell\}$, without restriction: the set entailed by $\langle [..] \rangle^{\{\ell\}}$. Now, when $R(\ell) = \perp \vee \perp$, there are two possibilities. The first is $\zeta = \rho$ and $\ell \in L$. There is a clash, and we subsume $\neg R$ to the top record type $\{[..]\}$ before deleting ℓ , as we did in the positive case. Note that $\{[..]\}$ is the smallest type to which we can subsume $\neg R$. The second possibility is given by the third case of the definition (i.e., the first case for the negated literal). There, it is impossible to have a value of a type different from $R(\ell) = \perp \vee \perp$. Hence, the constraints on the type must be on the other fields: we simply remove ℓ from the definition definition space of the row.

The language satisfies the property of soundness. Its proof is routine (subject reduction and progress, using inversion and generation lemmas) and can be found in Appendix B.

THEOREM 3.1 (TYPE SOUNDNESS). *Let e be a well-typed closed expression, that is, $\emptyset \mid \emptyset \vdash_{\mathcal{D}} e : t$ for some t . Then either e diverges or it reduces to a value of type t .*

3.2 Algorithmic Type System

The system in Fig. 1 is not algorithmic: it is not syntax-directed and some of its rules are not analytic¹². In Fig. 2, we give an algorithmic system that is sound and complete with respect to the system in Fig. 1 (we omitted three rules that are the same as in Fig. 1). The new system includes the algorithmic counterparts of the typing rules for record operations which, apart from (EMP), must be changed to account for the fact that there is no (INST) rule in the algorithmic system and, thus, instantiation must be performed by the algorithmic elimination rules. For instance, in the declarative system, if $x : \alpha$ and $\alpha \notin \Delta$, then $x.\ell : \text{Int}$ can be deduced by instantiating by (INST) α to $\{\ell = \text{Int}[..]\}$. In the algorithmic system, in the absence of (INST), this instantiation must be done within the algorithmic rule (SEL). For all record operations, the algorithmic system needs to perform a possible instantiation of the type of the record. This is done in the side conditions of the rules for record operations by the following operators (that we explain after the Definition 3.2 for \sqsubseteq_{Δ}), which instantiate the type of the record to match the conditions in the declarative system:

$$\begin{aligned}
\Pi_{\Delta}^{\ell}(t) &= \{t' \mid [\sigma_i]_{i \in I} \Vdash t \sqsubseteq_{\Delta} \{\ell = \perp \mid ..\} \text{ and } t' = (\wedge_{i \in I} t\sigma_i).\ell\} \\
t \odot_{\Delta} \ell &= \{r \mid [\sigma_i]_{i \in I} \Vdash t \sqsubseteq_{\Delta} \{[..]\} \text{ and } r = (\wedge_{i \in I} t\sigma_i) \setminus \ell\} \\
t \odot_{\Delta}^{\perp} \ell &= \{r \mid [\sigma_i]_{i \in I} \Vdash t \sqsubseteq_{\Delta} \{\ell = \perp \mid ..\} \text{ and } r = (\wedge_{i \in I} t\sigma_i) \setminus \ell\}
\end{aligned}$$

¹²A rule is *analytic* (as opposed to *synthetic*) when the input (i.e., Γ and e) of the judgment at the conclusion is sufficient to determine the inputs of the judgments at the premises (cf. [33, 46]).

These side conditions are primarily of theoretical interest to satisfy completeness. They address the case of record expressions that return (parametric) polymorphic values (e.g., of type α), which are never encountered in practice. Consequently, the sets in these side conditions are never computed in practice. In a practical setting, the rules (EXT) and (DEL) of Fig. 1 should be used instead, while the rule to use in practice for selection has premises $\Delta \mid \Gamma \vdash_{\mathcal{A}} e : t$, side-condition $t \leq \{\ell = \mathbb{1} \mid ..\}$, and conclusion $\Delta \mid \Gamma \vdash_{\mathcal{A}} e.\ell : t.\ell$. Keeping the rules of Fig. 1, we lose completeness, but only in theory, and we gain in efficiency ([10, Appendix B.3] discusses this point in detail for type polymorphism).

In any case, selection uses a new type operator $t.\ell$ (theoretically, in its side condition to compute t' ; in practical setting, in its conclusion). Since the algorithmic type system does not include a subsumption rule, we cannot assume that the type t deduced for the expression e in (SEL) will be a record type atom of the form required by the declarative system (i.e., $\{\ell = t \mid ..\}$): in general, t will be a union of intersections of such atoms, type variables, and their negations. Thus the rule checks that t is a record type in which the field ℓ is surely defined, and delegates to the operator $t.\ell$ (defined below) the computation of the type of the result.

DEFINITION 3.1 (FIELD SELECTION). *Let $t \leq \{\ell = \mathbb{1} \mid ..\}$ be a DNF. We define the selection of the field ℓ of t as $(\bigvee_{i \in I} t_i).\ell \stackrel{\text{def}}{=} \bigvee_{i \in I} t_i.\ell$ and*

$$\left(\bigwedge_{R \in P} R \wedge \bigwedge_{R \in N} \neg R \wedge \bigwedge_{\alpha \in V_p} \alpha \wedge \bigwedge_{\alpha \in V_n} \neg \alpha \right).\ell \stackrel{\text{def}}{=} \bigvee_{N' \subseteq N} \left(\bigwedge_{R \in P} R(\ell) \wedge \bigwedge_{R \in N'} \neg R(\ell) \right)$$

The condition $t \leq \{\ell = \mathbb{1} \mid ..\}$ assures that $t.\ell \leq \mathbb{1}$, so that selection always returns a type (and not a generic field-type). Indeed, $t.\ell$ is equivalent to $\min\{t' \mid t \leq \{\ell = t' \mid ..\}\}$ (Appendix B.2). Once more, the presence of top-level intersections with type variables does not play any role in selection.

To finish explaining the algorithmic system, we need to introduce the notations $t \sqsubseteq_{\Delta} t'$ and $t \bullet_{\Delta} t'$, whose definitions are taken verbatim from [10]:

DEFINITION 3.2 ([10]). *Let t and t' be two types and Δ a set of variables.*

$$\begin{aligned} [\sigma_i]_{i \in I} \Vdash t \sqsubseteq_{\Delta} t' &\stackrel{\text{def}}{\iff} \bigwedge_{i \in I} t\sigma_i \leq t' \text{ and } \forall i \in I. \text{dom}(\sigma_i) \cap \Delta = \emptyset \\ \Vdash t \sqsubseteq_{\Delta} t' &\stackrel{\text{def}}{\iff} \exists [\sigma_i]_{i \in I} \text{ such that } [\sigma_i]_{i \in I} \Vdash t \sqsubseteq_{\Delta} t' \end{aligned}$$

DEFINITION 3.3 ([10]). *Let t_1 and t_2 be two types with $t \leq \mathbb{0} \rightarrow \mathbb{1}$, and Δ a set of variables. We define $t_1 \bullet_{\Delta} t_2$ as the set of types for which there exist two sets of type substitutions (for variables not in Δ) that make t_2 compatible with the domain of t_1 (defined below):*

$$t_1 \bullet_{\Delta} t_2 \stackrel{\text{def}}{=} \left\{ t \mid \begin{array}{l} [\sigma_j]_{j \in J} \Vdash t_1 \sqsubseteq_{\Delta} \mathbb{0} \rightarrow \mathbb{1} \\ [\sigma_i]_{i \in I} \Vdash t_2 \sqsubseteq_{\Delta} \mathbf{dom}(\bigwedge_{j \in J} t_1\sigma_j) \\ t = \bigwedge_{j \in J} t_1\sigma_j \cdot \bigwedge_{i \in I} t_2\sigma_i \end{array} \right\}$$

Where $t_1 \cdot t_2 \stackrel{\text{def}}{=} \min\{t \mid t \leq t_1 \rightarrow t_2\}$. For an arrow type $t' \leq \mathbb{0} \rightarrow \mathbb{1}$, we have $t' \simeq \bigvee_{i \in I} (\bigwedge_{p \in P_i} (t_p \rightarrow t'_p) \wedge \bigwedge_{n \in N_i} \neg(t_n \rightarrow t'_n) \wedge \bigwedge_{\alpha \in V_p^i} \alpha \wedge \bigwedge_{\alpha \in V_n^i} \neg \alpha)$, and define $\mathbf{dom}(t') = \bigwedge_{i \in I} \bigvee_{p \in P_i} t_p$.

These two definitions are used in the rule (APP), the key rule for the algorithmic system (which again is taken verbatim from [10] where more details can be found). Essentially, (APP) merges together intersection elimination (in this case the standard terminology is *expansion*), instantiation, and subsumption. For the application $e_1 e_2$ to be well typed, the type of the function must be a functional type (i.e., a subtype of $\mathbb{0} \rightarrow \mathbb{1}$, the type of all functions) whose domain is a supertype of the type of the argument. Therefore, the rule looks for two finite sets of type substitutions for the variables not in Δ , that make the type of the function subtype of $\mathbb{0} \rightarrow \mathbb{1}$ and the type of the argument subtype of the function's domain. This search is collapsed in the definition of $t_1 \bullet_{\Delta} t_2$. Concretely, this operation finds two sets of substitutions $[\sigma_j]_{j \in J}$ and $[\sigma_i]_{i \in I}$ such that (1) $\bigwedge_{j \in J} t_1\sigma_j \leq \mathbb{0} \rightarrow \mathbb{1}$

(this corresponds to the notation $t_1 \sqsubseteq_{\Delta} 0 \rightarrow \mathbb{1}$ of [Definition 3.2](#)) and (2) $\bigwedge_{i \in I} t_2 \sigma_i$ is a subtype of the domain of $\bigwedge_{j \in J} t_1 \sigma_j$. It then returns all the types of the result of the application of such two types.

The operator \sqsubseteq_{Δ} is also used to type record operations, since it is used by the side conditions of the algorithmic rules (DEL), (SEL), and (EXT): when applying an operation on a record expression e of type t , these side conditions check whether there exists a set of substitutions making t a subtype of, depending on the rule, $\{\ell = \mathbb{1} | ..\}$, $\{ | ..\}$, or $\{\ell = \perp | ..\}$ and, if so, they apply the corresponding operation on the instantiation of t . For instance, $\Pi_{\Delta}^{\ell}(t)$ looks for some substitutions $[\sigma_i]_{i \in I}$ such that $\bigwedge_{i \in I} t \sigma_i \leq \{\ell = \mathbb{1} | ..\}$ (i.e., a solution for $t \sqsubseteq_{\Delta} \{\ell = \mathbb{1} | ..\}$) and returns its projection on ℓ .

Finally, notice that, even if the typing rules (ABS) and (APP) themselves are not new, the process behind $t_1 \sqsubseteq_{\Delta} t_2$ and $t_1 \bullet_{\Delta} t_2$ are. The novelty is that these operators now infer type substitutions that range not only over types, but also over rows and field-types. In the next section, we describe how to adapt the existing algorithms to our framework.

As expected, the algorithmic type system is sound and complete with respect to the declarative one, as stated by the following theorems (proofs are given in [Appendix B.2](#)):

THEOREM 3.2 (SOUNDNESS). *If $\Delta \mid \Gamma \vdash_{\mathcal{A}} e : t$, then $\Delta \mid \Gamma \vdash_{\mathcal{D}} e : t$.*

THEOREM 3.3 (COMPLETENESS). *If $\Delta \mid \Gamma \vdash_{\mathcal{D}} e : t$, then there is t' such that $\Delta \mid \Gamma \vdash_{\mathcal{A}} e : t'$ and $t' \sqsubseteq_{\Delta} t$.*

3.3 Tallying

The algorithmic type system we have defined is parametric in the decision procedure $s \sqsubseteq_{\Delta} t$, which looks for an appropriate set of substitutions $[\sigma_i]_{i \in I}$ such that $\bigwedge_{i \in I} s \sigma_i \leq t$. While this has been tackled for type variables by Castagna et al. [10], here we need to extend the procedure to row and field variables along the lines we outline below (for a full description, see the [Appendix C](#)).

Deciding $t_1 \sqsubseteq_{\Delta} t_2$ is done by testing the cardinality of the set of substitutions $[\sigma_i]_{i \in I}$ we are looking for, by incremental steps. For $t_1 \bullet_{\Delta} t_2$, two sets of substitutions are sought for, and we can follow a dove-tail order (more details are in [10, §3.2.2-3.2.3]).

For each cardinality, we apply an instance of the *tallying* algorithm. Tallying is a unification problem acting on inequalities. Given an initial set of subtyping constraints, tallying looks for a substitution that satisfies these constraints. For instance, deciding $t_1 \sqsubseteq_{\Delta} t_2$ is done first by trying to solve the tallying problem for the constraint (t_1, \leq, t_2) , looking for a singleton substitution set. In case of a (non-fatal) failure, the next step is to look for a set of two substitutions such that $[\sigma_1, \sigma_2] \Vdash t_1 \sqsubseteq_{\Delta} t_2$, which is equivalent to solving the tallying problem for the constraint $(t_1^1 \wedge t_1^2, \leq, t_2)$, where each t_1^i is obtained from t_1 by replacing all variables not in Δ by fresh ones.

Tallying returns a set of constraint-sets. Indeed, the presence of subtyping, and in particular of the empty type, implies that to solve a single set of constraints C we may need to generate several sets of constraints, yielding different solutions. For instance, solving $\{(\{\ell_1 = t_{\ell_1}, \ell_2 = t_{\ell_2} | ..\}, \leq, \{\ell_1 = t'_{\ell_1}, \ell_2 = t'_{\ell_2} | ..\})\}$ generates three independent subproblems: $\{(t_{\ell_1}, \leq, 0)\}$, $\{(t_{\ell_2}, \leq, 0)\}$ and $\{(t_{\ell_1}, \leq, t'_{\ell_1}), (t_{\ell_2}, \leq, t'_{\ell_2})\}$.

We define the solving procedure for the type tallying of a constraint-set as an extension of the existing one for type variables. The procedure follows the steps that are given by [10] (plus an additional one), namely: (1) normalization, (2) merging and saturation, (3) harmonization (which is new and specific to row variables), (4) transformation of constraints into equations, and (5) creation of the substitution solutions. For space reasons, in what follows we only outline these steps. For formal definitions, refer to the [Appendices C.4 to C.8](#).

A constraint is defined as a triple (T_1, c, T_2) ($c \in \{\leq, \geq\}$) such that T_1 and T_2 are two terms of the same kind (type, field-type, or rows of the same domain). An arbitrary order on variables is given as an input to the algorithm in order to guarantee well-formedness of the solution.

Normalization. The first step of tallying decomposes the initial constraints on types into a set S of *normalized* constraint-sets. These are constraint-sets where all constraints are of the shape $\langle X, c, T \rangle$, where T stands for a type, field-type or row and X for a variable of the kind of T .

Normalization works by decomposing types into elementary constraints. For records and rows, it might be necessary to decompose the row variables across different fields. For instance, the record $\{\mid \rho_0\}$ might need to be decomposed over, say, labels ℓ_1 and ℓ_2 . In that case, we will spread the row variable ρ_0 into $\{\ell_1 = \rho_0.\ell_1, \ell_2 = \rho_0.\ell_2 \mid \rho_0 \setminus \{\ell_1, \ell_2\}\}$, introducing $\rho_0.\ell_1, \rho_0.\ell_2$ and $\rho_0 \setminus \{\ell_1, \ell_2\}$ as field and row variables with special names. Then, the tallying algorithm may give constraints over $\rho_0.\ell_1, \rho_0.\ell_2$ and $\rho_0 \setminus \{\ell_1, \ell_2\}$, and we expect a solution of the shape $\sigma(\rho_0) = \langle \ell_1 = \tau_1, \ell_2 = \tau_2 \mid r \rangle^0$, where each τ_i has been obtained from the constraints on $\rho_0.\ell_i$, and r from the ones on $\rho_0 \setminus \{\ell_1, \ell_2\}$.

In the literature where rows are all atomic, unification of a row variable with another row is performed component-wise. Considering each field independently, while it works well with atomic rows, is unsound when working with Boolean combination of rows, as shown by this example:

Example 3.4. Let $\text{result} = \langle \log = \text{String}, \text{succ} = \text{True}, \text{val} = \perp \mid \epsilon \rangle^0 \vee \langle \log = \text{String}, \text{succ} = \text{False}, \text{val} = \perp \mid \epsilon \rangle^0$. For the constraint $(\langle \text{val} = \perp \vee \perp \mid \rho \rangle^0, \leq, \text{result})$, independent component-wise tallying gives $\sigma(\rho) = \langle \log = \text{String}, \text{succ} = \text{Bool} \mid \epsilon \rangle^{\{\text{val}\}}$ as a solution, which does not verify the constraint (the type obtained as “solution” contains record values in which succ is True and val is undefined, which are not included in result). Indeed, such a procedure effectively solves tallying for $(\langle \text{val} = \perp \vee \perp \mid \rho \rangle^0, \leq, \langle \log = \text{String} \vee \text{String}, \text{succ} = \text{True} \vee \text{False}, \text{val} = \perp \vee \perp \mid \epsilon \rangle^0)$ instead. \square

To obtain a sound decomposition of rows, we can adapt the formula underlying our subtyping algorithm (this formula is found in the statement of [Lemma A.6](#)). Given a constraint C on DNFs of rows, we still consider the set L of all top-level labels in the DNFs (in the last example, $L = \{\log, \text{succ}, \text{val}\}$), for which we will end up with independent constraints and constraints over the cofinite domain of the rows deduced from L . Doing so, we find no solution for the constraint in [Example 3.4](#), which is correct, since indeed the constraint cannot be satisfied.

Although this method yields a correct set of solutions, this set is far from being complete: the more fields we decompose over, the more solutions we might loose. Yet, the previous method decomposes records and rows over the whole set of top-level labels. Our solution is to decompose rows over a set of labels as small as possible. This technique is based on a general decomposition formula given in the statement of [Lemma C.4](#). Now, while normalization is sound, the algorithm is still not complete, due to the potentially necessary decomposition of some row variables.

Example 3.5 (Incompleteness). Consider the constraint-set $\{(\langle \log = \text{String} \mid \rho_2 \rangle^0 \rightarrow \langle \log = \text{String} \mid \rho_2 \rangle^0, \geq, \text{result} \rightarrow \text{result}), (\langle \log = \text{String} \mid \rho_2 \rangle^0 \rightarrow \langle \perp \dots \rangle^0, \geq, \langle \text{succ} = \perp \vee \perp, \text{val} = \perp \vee \perp \mid \rho_1 \rangle^0 \rightarrow \langle \text{succ} = \perp \vee \perp, \text{val} = \perp \vee \perp \mid \rho_1 \rangle^0)\}$. Let ρ_1 be of smaller order than ρ_2 . By a decomposition over $L = \{\log\}$ in the first constraint and $L = \{\text{succ}, \text{val}\}$ in the second constraint, we derive the constraint-set (omitting trivial constraints) $\{(\text{String}, \leq, \rho_1, \log), (\rho_2 \setminus \{\text{succ}, \text{val}\}, \leq, \rho_1 \setminus \{\log\}), (\rho_2, \leq, \text{result}), (\rho_2, \geq, \text{result})\}$.

As we describe below (cf. *Harmonization*), a further step of the tallying algorithm harmonizes the decomposition of the row variables across all constraints. In particular, it decomposes ρ_2 over $\{\text{succ}, \text{val}\}$ in the constraints $(\rho_2, \leq, \text{result})$ and $(\rho_2, \geq, \text{result})$. Since when decomposing ρ_2 in this way, no solution might apply to both of these constraints (ρ_2 needs to be instantiated exactly to the union type result), tallying fails. The solution mapping ρ_2 to result is not found. \square

Constraint merging and saturation. After normalization, a constraint set may have for the same variable X different constraints of the form $T_1 \leq X, \dots, T_n \leq X$ and $X \leq T'_1, \dots, X \leq T'_m$: we replace them by two constraints $\bigvee_{1 \leq i \leq n} T_i \leq X$ and $X \leq \bigwedge_{1 \leq j \leq m} T'_j$, then we add $\bigvee_{1 \leq i \leq n} T_i \leq \bigwedge_{1 \leq j \leq m} T'_j$ to (i.e., saturate) the constraint set, and we normalize again.

Harmonization. Take a constraint-set C with $(\rho \setminus L_1, c, r) \in C$, $L_1 \subseteq L$ and L the set of labels appearing in the names of variables $\rho'.\ell$ and $\rho' \setminus L_2$ in C . As mentioned in [Example 3.5](#), harmonization of constraint-set rewrites the constraint $(\rho \setminus L_1, c, r)$ into $(\rho \setminus L, c, r)$ and feeds this constraint to normalization again. Harmonization ends with a constraint-set of homogeneous domain, where for each initial row variable ρ all occurrences of $\rho \setminus L$ are defined on (i.e., harmonized to) the same L .¹³

Equations generation. At this point, for each type and field variable X there are two unique constraints of the form $T \leq X$ and $X \leq T'$, that we transform into the equation $X = (T \vee X') \wedge T'$ with X' fresh. For a row variable ρ , there is a set of labels L and constraints of the form $\tau_1 \leq \rho.\ell \leq \tau_2$ for each $\ell \in L$, and a constraint $r_1 \leq \rho \setminus L \leq r_2$. We define the terms $\tau_\ell = (\tau_1 \vee \theta_\rho^\ell) \wedge \tau_2$ and $r = (r_1 \vee \rho') \wedge r_2$, with fresh variables θ_ρ^ℓ and ρ' . We finally create an equation $\rho = \langle (\ell = \tau_\ell)_{\ell \in L} \mid r \rangle_{\mathcal{L} \setminus \text{def}(\rho)}$.

Solution. We solve the equations following the given order on the variables on the left-hand side, by collecting the equations $X = T$ and replacing in all other equations X by $\mu X'.$ ($T\{X'/X\}$) with X' fresh. Thanks to the order, the type $\mu X'.$ ($T\{X'/X\}$) is contractive and, thus, well-formed.

A solution to a constraint-set C is a substitution σ such that $\forall (T_1, \leq, T_2) \in C. T_1 \sigma \leq T_2 \sigma$ and $\forall (T_1, \geq, T_2) \in C. T_1 \sigma \geq T_2 \sigma$ hold. If σ is a solution to C , we write $\sigma \Vdash C$.

3.3.1 Properties of the algorithm. We call $\text{Sol}_\Delta(C)$ the solving procedure for the type tallying of C . We write $\text{Sol}_\Delta(C) \rightsquigarrow \Theta$ if $\text{Sol}_\Delta(C)$ terminates yielding the set of substitutions Θ , called the *solution* of the type tallying problem for C .

THEOREM 3.6 (SOUNDNESS). *Let C be a constraint-set. If $\text{Sol}_\Delta(C) \rightsquigarrow \Theta$, then for all $\sigma \in \Theta$, $\sigma \Vdash C$.*

THEOREM 3.7 (TERMINATION). *Let C be a constraint-set. Then $\text{Sol}_\Delta(C)$ terminates.*

PROPOSITION 3.8. *Let C be a constraint-set and $\text{Sol}_\Delta(C) \rightsquigarrow \Theta$. Then (1) Θ is finite and (2) for all $\sigma \in \Theta$ and for all $X \in \text{dom}(\sigma)$, the types in $\sigma(X)$ are contractive.*

4 Related Work

Row polymorphism. Our formalization of records as quasi-constant total functions and the inclusion of row polymorphism are directly inspired from the formalism of Rémy [41, 42]. Rémy's work contains neither set-theoretic types nor subtyping, and therefore commutation of fields is obtained by structural equations. Unlike our case, the types in [42] are not recursive. An extension of this system to recursive types is given by [43] when describing a type system for objects.

Before Rémy, Wand [47] introduced row polymorphism to type object inheritance. His type inference algorithm, corrected in [48], considers free record extension (i.e., right priority record concatenation) but lacks principal solutions. Instead, it deduces a finite set of solutions of which all types of the term under consideration are instances, as we also do. However, unlike us, Wand's type grammar lacks intersection types, so it is not possible to merge the multiple solutions into a single type, as we instead do. In an earlier attempt of our work we considered free record extension, as it is present both in CDuce and in its generalization by Castagna [6], but this made the theory much more involved, in particular tallying. It would be worthwhile to study this possibility again, now that the theory with strict extension is precisely laid down. However, we anticipate this study to be quite complex: typing the concatenation of two polymorphic records presents significant challenges. It will likely require enriching the type algebra to explicitly represent row concatenations (row variables included), as the type operators used in CDuce for typing record concatenation are insufficient for this purpose.

¹³ This step introduces a multiplicative factor with respect to the complexity of the version of tallying without row polymorphism. This factor is expected to be low in practice, since it is bounded by the number of labels a programmer uses in a single type and by the number of constraints in which a variable appears.

(Syntactic) subtyping is present in the work of Cardelli and Mitchell [4]. Operations on records (deletion, selection, extension) are directly defined within the syntax of types. In our system instead, we compute these operations on the types during typing. It is thus currently impossible to postpone the extension or deletion of a field with label ℓ that is affected by a row variable, until the point where the row variable will be instantiated and, in that case, we must resort to an approximation. Cardelli and Mitchell must however define syntactic equivalence relations on operators and fields, and their system lacks principal typing, as well.

Row polymorphism and extensible records are implemented using predicate on types by Harper and Pierce [26] and, later, by Gaster and Jones [24] under the name qualified types. In the latter, positive information is given in the type and negative information (absent field) in the predicate. Morris and McKinna [35] use qualified types with uninterpreted predicates for concatenation and membership of fields. Their system can be instantiated to most of the standard approaches of the literature. We aimed to minimize changes to the type syntax of CDuce and Elixir, opting to refrain from incorporating qualified types. On the theory side, we wished to keep the implementation of records as total functions—as already present in the semantic subtyping framework—while in systems with qualified types, records are constructed from partial functions.

A convenient way to define extensible records is with scoped labels [31], where labels may appear several times in a record, the most recent occurrence shadowing earlier ones. Paszke and Xie [38] recently extended the formalism to deal with first-class labels, first-class rows and concatenation. This gives a simple formulation of types, albeit too syntactic for our semantic approach to typing and subtyping, and our desire to interpret records as quasi-constant functions. Using scoped labels would impose more structure on the interpretation of records, and therefore could weaken the intuitive understanding of set-like operations and types as sets.

Variants, the dual of records, are studied in a semantic subtyping setting by Castagna et al. [12], where they show that adopting full-fledged union (and intersection and negation) types as well as let-polymorphism gives a more intuitive and expressive theory of polymorphic variants. However, as we showed in Section 1.2, our semantic interpretation seems to break this duality, insofar as these same features are not enough to encode record polymorphism too.

Presence polymorphism. Rémy [42] describes records types with fields that can be either present or absent, as indicated by an additional annotation. He shows how to add presence polymorphism over these annotations, yielding records parametric in the absence or presence of some fields. Garrigue [23] proposes a weaker system, where constraints apply to single variables (rather than being distributed over row and presence variables), and where absent fields are determined by intersecting type constraints. Garrigue [23] justifies this choice by the fact that it yields types that are simpler to understand, since they do not require different variables of different sorts. This simplicity is the reason why it is the system used for OCaml. Our work shares Garrigue’s simplicity, since only row variables are visible to the programmer and, under the hood, field-type variables—which range over types augmented with \perp —provide a natural notion of presence polymorphism. Field-type variables can be instantiated with \perp for an absent field, with a type t for a mandatory field, but also with $t \vee \perp$ for an optional field of type t . To our knowledge, our work is the first to allow presence polymorphism over optional fields: in the existing literature, instantiated field-types of polymorphic records can just be either present or absent, but not both. Moreover, integrating presence polymorphism in our framework is straightforward since field-type variables are almost handled as ordinary type variables: it is the kinding system that enables the extra \perp possibility (for an example-based comparison between presence polymorphism of [42] and ours, see Appendix A.2).

Relation between different kinds of polymorphism. Our type system features three kinds of parametric polymorphism: on types, rows, and field-types. It also features subtype polymorphism and

ad-hoc polymorphism via intersection and union types. The question naturally arises: how are these concepts interconnected, and where do they overlap? It is folklore that unrestricted intersections combined with parametric polymorphism encode a form of bounded quantification, as described in the introduction (see also [7, Section 2]). Tang et al. [45] formally compare the expressiveness of row and presence polymorphism to *structural* subtyping, for calculi with records and variants. More precisely, they encode diverse subtyping using relevant polymorphic systems. Whether their techniques can be adapted to gather insights into semantic subtyping, or polymorphism in the semantic subtyping framework, remains an open question.

Xie et al. [50] show that row and bounded polymorphism can be encoded with disjoint polymorphism, obtained by adding parametric polymorphism to a system with *disjoint* intersections, and having a disjointness predicate in the quantification of types. Contrary to our intersections, that are uninhabited if applied to separate types, disjoint intersections type a merge operator that generalizes the disjoint concatenation of extensible data types, like records, to arbitrary types. The deletion operator of extensible data types can also be generalized to arbitrary types using disjoint polymorphism and a merge operator. This operator once again differs from our set exclusion operation $t_1 \setminus t_2 = t_1 \wedge \neg t_2$.

Parreaux and Chau [37] present MLstruct, an extension with set-theoretic types of MLsub [14], based on *algebraic subtyping*. Their approach differs from ours, as it provides less expressive subtyping and type connectives. For instance, intersections cannot type general overloaded functions, and a union of records in MLstruct is equivalent to the single record with the union applied component-wise. Keeping unions of records distinct is a crucial feature of our system (cf., the code in lines 23 to 29 in the introduction) and a major difficulty for the tallying problem. The gain from this reduced expressivity is the existence of principal types (a property absent in semantic subtyping even for simple monomorphic types), the ability to encode record extension and deletion without the need for row polymorphism, and maintaining the duality between variants and records.

Effect systems. Record calculi and row polymorphism had a significant impact on effect systems. As suggested by an anonymous reviewer, our work may usefully apply to that setting. For instance, in the language Koka [32], the introduction of row polymorphism for effects is justified by the fact that inference cannot solve constraints for unions. This yields to approximations as the ones we pointed out in the last examples of Section 1.2. But in our system we are able to keep separate unions while having row polymorphism. This should in principle allow the system to track effects more finely than in [32]. For instance, consider this example directly derived from [32]

```
function foo(f,g) { if (random()) then { f(); error("hi") } else { g(); print("hi") } }
```

If $t_1 \rightarrow \varepsilon t_2$ is the type of functions that can be applied to an input t_1 and produce an output of type t_2 and effect ε , then using our row polymorphism we should be able to give the example above the type $\forall \varepsilon_1 \varepsilon_2. (() \rightarrow \langle |\varepsilon_1 \rangle () , () \rightarrow \langle |\varepsilon_2 \rangle () \rangle \rightarrow ((\langle \text{rnd}, \text{exn} | \varepsilon_1 \rangle \cup \langle \text{rnd}, \text{io} | \varepsilon_2 \rangle) ())$, which states that `foo` can either produce the `exn` effect (by erroring) or the `io` effect (by printing) but not both. The system for Koka would not be able to distinguish the two effects. This suggests that exploring the use of our system in effect systems could be a fruitful direction for future work.

Practice. Efficient compilation of polymorphic or extensible records has been widely explored by researchers such as Gaster and Jones [24], Ohori [36]. These works advocate moving away from Rémy's formalism. Ohori's calculus, in particular, stores information in elaborated kinds. It was expanded to extensible records by Alves and Ramos [1], but with no mention of the compilation method. Yet, Hillerström and Lindley [27] provide a compelling abstract machine for a calculus employing this formalism, serving as a foundation for their language Links. Regarding general-purpose languages, several of them propose either a flavor of set-theoretic types (like Typescript [34] or Flow [18]), sometimes based on the theory of semantic subtyping (CDuce, Luau [30], Elixir [16],

or Ballerina [2]), or polymorphic extensible records (like Purescript [19] or OCaml) but, to our knowledge, none of them offers both of these features, as we propose in this work.

5 Conclusion

We designed a type system featuring set-theoretic types and semantic subtyping for record calculi with row and presence polymorphism. We instantiated this type system on a specific λ -calculus incorporating record selection, extension, and deletion, and devised a unification (*tallying*) algorithm. We believe there are at least five key takeaways from our work:

- (1) *Intersection types and parametric polymorphism fall short*: while their combination is expressive, it cannot fully address practical examples that row polymorphism can handle effectively.
- (2) *Surprising similarity in subtyping algorithms*: the subtyping algorithms for monomorphic and polymorphic records are strikingly and disturbingly similar. This similarity is “disturbing” because of the extensive effort we had to put in to finally prove that the polymorphic case is obtained from the monomorphic case by adding just a single non-recursive case that tests whether a row variable belongs to a finite set.
- (3) *Comparable type inference*: from an algorithmic and complexity perspective, type inference for row variable polymorphism closely parallels that for parametric polymorphism.
- (4) *Distinct semantics*: records represent total functions on the set of all labels, while rows (and consequently row variables) represent partial functions. This subtle distinction introduces significant challenges and subtleties in the formal treatment.
- (5) *Set-theoretic types disrupt type dualities*: incorporating set-theoretic types and semantic subtyping undermines the traditional duality between variant and record types.

Our next goal is to implement our results in the CDuce compiler, thereby enhancing the language with row polymorphism. We closely adhered to the theory used for CDuce, in that record types were simply extended with row variables and presence polymorphism, leveraging the union connective and an existing constant for undefinedness. Our model and algorithms, specifically for subtyping and tallying, naturally extend the existing ones, therefore their implementation will not affect the performance of the type-checker. While we did not address the problem of type reconstruction, Castagna et al. [9] provide the theory and an implementation of type reconstruction for an ML-like language that uses CDuce’s tallying library as a black box. We are confident that integrating our tallying algorithm into that system and adding records to the language should yield, with some extra effort, a reconstruction system with polymorphic records.

CDuce is, of course, more complex than our record calculus. Likewise, any type system for a dynamic language needs to account for features like pattern matching, type cases, guards, or type narrowing. At first sight, these features seem mostly orthogonal to the introduction of row polymorphism. Our hope is to be able to integrate the latter seamlessly into any existing set-theoretic type system with semantic subtyping, such as Elixir [8], Ballerina [2], Luau [30], or Erlang [44]. We are closely monitoring the ongoing efforts to port CDuce’s tallying algorithm into the Elixir compiler.

Our record calculus lacks first-class labels. Castagna [6] defines a system in which records can be used both as “structs” (i.e., records without first-class labels) and as dictionaries/maps with first-class labels. His work is carried out in the same setting as ours, set-theoretic types and records as quasi-constant functions, but without row polymorphism. However, some solutions proposed by Castagna [6] are explicitly motivated by having a system that could be easily extended with row and presence polymorphism, which is why we believe that merging the two systems should not pose any fundamental issue. The actual expressiveness of a system with first-class labels where operations on records are not part of the syntax of types remains to be investigated.

Data Availability Statement

Additional definitions, proofs, and extensions omitted from the main text can be found in the appendix. This appendix is available online both in the ACM Digital Library and in the Arxiv repository at <https://arxiv.org/abs/2404.00338>.

Acknowledgments

This work benefitted from the valuable feedback of individuals working on Elixir and semantic subtyping: Guillaume Duboc, Kim Nguyen, and José Valim. In particular, José directed us to the logger module, which we used for our examples in Section 1.1. We also thank the anonymous reviewers for their insightful comments and suggestions, especially one reviewer who highlighted the connection with effect systems discussed in Section 4. This work was partially supported by a CIFRE grant n°2021/0420 to develop the type system of Elixir and by the Horizon Europe ERC Starting Grant CRETE (GA:101039196).

A APPENDIX FOR TYPES

A.1 Kinding System

The kinding rules for types are given in Fig. 3.

$$\begin{array}{c}
 \frac{}{\emptyset : \kappa} \quad \frac{t : \kappa}{\neg t : \kappa} \quad \frac{t_1 : \kappa \quad t_2 : \kappa}{t_1 \vee t_2 : \kappa} \quad \frac{}{\alpha : \star} \quad \frac{}{b : \star} \quad \frac{t_1 : \star \quad t_2 : \star}{t_1 \rightarrow t_2 : \star} \\
 \\
 \frac{\langle (\ell = \tau_\ell)_{\ell \in L} \mid \zeta \rangle^\emptyset : \text{Row}(\emptyset)}{\langle (\ell = \tau_\ell)_{\ell \in L} \mid \zeta \rangle : \star} \quad \frac{\forall \ell \in L_1. \tau_\ell : \star_\perp \quad \zeta \in \{\epsilon, ..\}}{\langle (\ell = \tau_\ell)_{\ell \in L_1} \mid \zeta \rangle^{L_2} : \text{Row}(L_2)} \quad L_1 \cap L_2 = \emptyset \\
 \\
 \frac{\forall \ell \in L_1. \tau_\ell : \star_\perp}{\langle (\ell = \tau_\ell)_{\ell \in L_1} \mid \rho \rangle^{L_2} : \text{Row}(L_2)} \quad L_1 \cap L_2 = \emptyset \quad \text{def}(\rho) = \mathcal{L} \setminus (L_1 \cup L_2) \quad \frac{}{\theta : \star_\perp} \quad \frac{}{\perp : \star_\perp} \quad \frac{t : \star}{t : \star_\perp}
 \end{array}$$

A.2 Example of a Presence Polymorphic Type

Presence polymorphism has been introduced by Rémy [42] to let a field be polymorphic in its presence. A presence variable θ can be instantiated to one of $\{\text{abs}, \text{pre}\}$. Our calculus also supports presence polymorphism thanks to field variables. Let us reproduce an example of a presence polymorphic type declaration from [42], that we will then transcribe to our setting.

30 `type tree(θ) = Leaf of Int | Node of {left:pre.tree(θ), right:pre.tree(θ), annot: θ .int}`

Instantiating θ to `abs` gives the type of trees with no annotations on the nodes, while instantiating it with `pre` gives the type of trees with integers annotated on the nodes.

But there are several problems: adding yet another kind of polymorphism adds a bit of work, and most of all, even absent fields must have a type attached. In [42], this can cause losing unification of two semantically equivalent records, if for instance one has a field ℓ of type `abs.int`, and the other a field ℓ of type `abs.bool`. To avoid this problem, Tang et al. [45] requires every record value to be annotated with its type, so that they can forget about absent types, and also so that they can have deterministic typing. So for instance the superfluous type $\{\ell_1 = M; \ell_2 = N\}^{\{\ell_1:\text{pre}.A; \ell_2:\text{abs}.B\}}$ is equivalent to $\{\ell_1 = M\}^{\{\ell_1:\text{pre}.A\}}$.

In CDuce, there is no presence polymorphism at all, and the tree type defined previously cannot be expressed without code redundancy. In our formalism, presence polymorphism is simply obtained by means of field variables, and adding support for it in CDuce would make it possible to write the following (note that we use unions instead of tagged unions):

31 `type tree(θ) = Int | {left:tree(θ), right:tree(θ), annot: θ }`

Fields do not have any superfluous type information when they are absent, so we do not have the redundant record expressions, and do not need to put type annotations directly on the values. Moreover, in CDuce and in our type system, fields can be optional. This is achieved thanks to union types (an optional field is encoded as $t \vee \perp$). We do not know of any presence polymorphic type system dealing with optional types.

We could instantiate the type of the example to any field-type, such as `Int` for a tree with all nodes annotated by an integer, `Int \vee \perp` for a tree with some nodes annotated by an integer, `\perp` for a tree with no annotation, and even for instance to a type variable α , to create a type parametric in

the type of its annotation, but where the annotation is mandatory on every node. In Rémy’s system, having polymorphism also on the type of the annotations would require having two parameter variables (for presence and for type).

A.3 Models

In this section we give the detailed technical development to define our subtyping relation.

To interpret record values we follow Frisch [20] and represent a record value by a quasi-constant function that maps labels into either values (i.e., the elements of \mathcal{D}) or \perp . Quasi-constant functions are total functions that map all but a finite set of elements of their domain into the same value (called default value). Thus record values can be represented by quasi-constant functions whose default value is \perp (see Castagna [6] for a more detailed explanation). Formally, let us write \mathcal{D}_\perp for $\mathcal{D} \cup \{\perp\}$ where \perp is a distinguished element not in \mathcal{D} . We represent our record values as quasi-constant functions from \mathcal{L} to \mathcal{D}_\perp and, thus, interpret record types as sets of these functions.

The formal definition of quasi-constant function has been given in Definition 2.2 and is repeated below for convenience.

DEFINITION 2.2 ([20]). *A function $r : \mathcal{L} \rightarrow \mathcal{D}_\perp$ is quasi-constant if the set $\{\ell \in \mathcal{L} \mid r(\ell) \neq \perp\}$ is finite. We use $\mathcal{L} \rightarrow \mathcal{D}_\perp$ to denote the set of quasi-constant functions from \mathcal{L} to \mathcal{D}_\perp and $\{\ell_1 = \delta_1, \dots, \ell_n = \delta_n, _ = \perp\}$ to denote the quasi-constant function $r : \mathcal{L} \rightarrow \mathcal{D}_\perp$ defined by $r(\ell_i) = \delta_i$ for $i = 1..n$ and $r(\ell) = \perp$ for $\ell \in \mathcal{L} \setminus \{\ell_1, \dots, \ell_n\}$.*

Although this notation is not univocal (unless we require $z_i \neq z$ and the ℓ_i ’s to be pairwise distinct), this is largely sufficient for the purposes of this work. If $(Z_\ell)_{\ell \in \mathcal{L}}$ is a family of subsets of Z indexed by \mathcal{L} , we denote by $\prod_{\ell \in \mathcal{L}} Z_\ell$ the subset of $\mathcal{L} \rightarrow Z$ formed by all quasi-constant functions r such that $r(\ell) \in Z_\ell$ for all $\ell \in \mathcal{L}$ (intuitively, $\prod_{\ell \in \mathcal{L}} Z_\ell$ is a “type” of quasi-constant functions).

Next we have to give an interpretation for the variables. Castagna and Xu [13] tell us that type variables must be interpreted as sets in the domain \mathcal{D} . Therefore, an interpretation for type variables is a function in $\mathcal{V}_t \rightarrow \mathcal{P}(\mathcal{D})$. Field variables are not much harder, since the only difference with type variables is that their interpretation can contain \perp , and therefore it is a function in $\mathcal{V}_f \rightarrow \mathcal{P}(\mathcal{D}_\perp)$. More difficult is the interpretation of row variables, since these are mapped into rows, that is, *partial* quasi-constant functions on \mathcal{L} . Let us write $\mathcal{L} \dashv \rightarrow \mathcal{D}_\perp$ for the partial quasi-constant functions from \mathcal{L} to \mathcal{D}_\perp . Thus, an interpretation of row variables must map an element of \mathcal{V}_r into a set of functions in $\mathcal{L} \dashv \rightarrow \mathcal{D}_\perp$. However, for a given ρ we cannot consider any element in $\mathcal{P}(\mathcal{L} \dashv \rightarrow \mathcal{D}_\perp)$: we need that the functions in the interpretation of ρ are total on $\text{def}(\rho)$. Formally, we have:

DEFINITION A.1 (WELL-KINDED INTERPRETATION). *Let η be a function in $\mathcal{V}_r \rightarrow \mathcal{P}(\mathcal{L} \dashv \rightarrow \mathcal{D}_\perp)$. We say that η is well kinded if for every $\rho \in \mathcal{V}_r$ and for every $f \in \eta(\rho)$, f is a (total) quasi-constant function in $\text{def}(\rho) \rightarrow \mathcal{D}_\perp$. We denote by $\mathcal{V}_r \Rightarrow \mathcal{P}(\mathcal{L} \dashv \rightarrow \mathcal{D}_\perp)$ the set of well-kinded functions.*

In conclusion our interpretation of types will be parametric in an assignment η for the variables, which will be a function in

$$\mathcal{H} \stackrel{\text{def}}{=} (\mathcal{V}_t \rightarrow \mathcal{P}(\mathcal{D})) \cup (\mathcal{V}_f \rightarrow \mathcal{P}(\mathcal{D}_\perp)) \cup (\mathcal{V}_r \Rightarrow \mathcal{P}(\mathcal{L} \dashv \rightarrow \mathcal{D}_\perp))$$

The next step is to define the domain \mathcal{D} in which to give the interpretation of types. This is quite simple for us since it suffices to take the model defined by Castagna and Xu [13] and replace products by quasi-constant functions. The hard problem for defining this model, and thus the interpretation of types, is to give an interpretation of the function spaces, but this problem was solved by Frisch et al. [22] whose solution is reused by Castagna and Xu [13]. In a nutshell we want to define an interpretation function $\llbracket \cdot \rrbracket : \mathcal{T} \rightarrow \mathcal{H} \rightarrow \mathcal{P}(\mathcal{D})$. Since the elements of \mathcal{D} represent the values of the language, then \mathcal{D} must contain the set C of constants of the language, the quasi-constant

functions (to represent record values), and the functions from \mathcal{D} to \mathcal{D} , but the last containment is impossible for cardinality reasons. The solution by [22] is to associate to every domain \mathcal{D} and function $\llbracket \cdot \rrbracket : \mathcal{T} \rightarrow \mathcal{H} \rightarrow \mathcal{P}(\mathcal{D})$ a unique *extensional interpretation* $\mathbb{E}(\cdot) : \mathcal{T} \rightarrow \mathcal{H} \rightarrow \mathcal{P}(\mathbb{E}_{\mathcal{D}})$ which fixes the semantic of the type constructors, and then to accept as a valid interpretation of the types only the pairs $(\llbracket \cdot \rrbracket, \mathcal{D})$ such that for all η , $\llbracket t \rrbracket_{\eta} = \emptyset \iff \mathbb{E}(t)_{\eta} = \emptyset$.

We invite the reader to refer to Castagna and Xu [13, Section 2.2] for a more detailed explanation of how the extensional interpretation works and to Frisch et al. [22] for full details. Henceforth, we just present how to extend the extensional interpretation of Castagna and Xu [13] to include quasi-constant functions and the interpretation of row-variables, and pinpoint the differences between the two definitions. We suppose to be given an interpretation $\mathbb{B} : \mathcal{B} \rightarrow \mathcal{P}(C)$ of basic types into sets of constants. Given a set S we use the notation \overline{S} to denote its complement in an appropriate universe: this notation is in particular used for the set $\mathcal{P}(\llbracket t_1 \rrbracket \times \llbracket t_2 \rrbracket)$ which corresponds to interpreting the elements in $t_1 \rightarrow t_2$ as binary relations, namely as elements of the set $\{ f \subseteq \mathcal{D}^2 \mid \text{for all } (d_1, d_2) \in f, \text{ if } d_1 \in \llbracket t_1 \rrbracket_{\eta} \text{ then } d_2 \in \llbracket t_2 \rrbracket_{\eta} \}$.

DEFINITION A.2 (EXTENSIONAL INTERPRETATION). *Let \mathcal{D} be a set. The extensional domain of \mathcal{D} is defined as: $\mathbb{E}_{\mathcal{D}} = C + \mathcal{D} + \mathcal{P}(\mathcal{D} \times \mathcal{D}_{\Omega}) + (\mathcal{L} \rightarrow \mathcal{D}_{\perp})$ where Ω and \perp are two different distinguished elements not in \mathcal{D} .*

Let $\llbracket \cdot \rrbracket : \mathcal{T} \rightarrow \mathcal{H} \rightarrow \mathcal{P}(\mathcal{D})$ be an interpretation of types parametric in a well-kinded interpretation of variables. The associated extensional interpretation of types is the unique function $\mathbb{E}(\cdot) : \mathcal{T} \rightarrow \mathcal{H} \rightarrow \mathcal{P}(\mathbb{E}_{\mathcal{D}})$ such that:

$$\begin{aligned} \mathbb{E}(\emptyset)_{\eta} &= \emptyset \\ \mathbb{E}(\alpha)_{\eta} &= \eta(\alpha) \\ \mathbb{E}(b)_{\eta} &= \mathbb{B}(b) \\ \mathbb{E}(\neg t)_{\eta} &= \mathbb{E}_{\mathcal{D}} \setminus \mathbb{E}(t)_{\eta} \\ \mathbb{E}(t_1 \vee t_2)_{\eta} &= \mathbb{E}(t_1)_{\eta} \cup \mathbb{E}(t_2)_{\eta} \\ \mathbb{E}(t_1 \rightarrow t_2)_{\eta} &= \mathcal{P}(\llbracket t_1 \rrbracket_{\eta} \times \llbracket t_2 \rrbracket_{\eta}) \end{aligned} \quad \mathbb{E}(R)_{\eta} = \begin{cases} \bigcup_{\bar{a} \in \eta(\rho)} \left(\prod_{\ell \in \text{lab}(R)} \llbracket R(\ell) \rrbracket_{\eta}^{\text{fld}} \sqcup \bar{a} \right) & \text{if } \text{tail}(R) = \rho \\ \prod_{\ell \in \mathcal{L}} \llbracket R(\ell) \rrbracket_{\eta}^{\text{fld}} & \text{otherwise} \end{cases}$$

where

$$\begin{aligned} \llbracket t \rrbracket_{\eta}^{\text{fld}} &= \llbracket t \rrbracket_{\eta} & \text{if } t \neq \neg t' \text{ and } t \neq t_1 \vee t_2 \\ \llbracket \emptyset \rrbracket_{\eta}^{\text{fld}} &= \eta(\emptyset) \\ \llbracket \perp \rrbracket_{\eta}^{\text{fld}} &= \{\perp\} \end{aligned} \quad \begin{aligned} \llbracket \tau_1 \vee \tau_2 \rrbracket_{\eta}^{\text{fld}} &= \llbracket \tau_1 \rrbracket_{\eta}^{\text{fld}} \cup \llbracket \tau_2 \rrbracket_{\eta}^{\text{fld}} \\ \llbracket \neg \tau \rrbracket_{\eta}^{\text{fld}} &= (\mathbb{E}_{\mathcal{D}} \cup \{\perp\}) \setminus \llbracket \tau \rrbracket_{\eta}^{\text{fld}} \end{aligned}$$

Notice that the induction used in the definition is well-founded thanks to the contractivity condition in the definition of types and the fact that field-types are inductively defined.

The extensional interpretation is defined with respect to some domain \mathcal{D} and interpretation $\llbracket \cdot \rrbracket$, and maps types into a domain $\mathbb{E}_{\mathcal{D}}$ that contains \mathcal{D} , constants C to interpret basic types, sets of binary relations $\mathcal{P}(\mathcal{D} \times \mathcal{D}_{\Omega})$ to interpret function types, and quasi constant functions $\mathcal{L} \rightarrow \mathcal{D}_{\perp}$ to interpret record types. The fact that functions are binary relations that can yield a distinguished element Ω (which, intuitively, represents a type error) is a standard technique of semantic subtyping to avoid $\mathbb{1} \rightarrow \mathbb{1}$ to be a supertype of all function types: since it does not play any specific role in our work we will not further comment on it (see [22] for a detailed explanation or Castagna [6, Section 3.2] for a shorter one).

The definitions for the extensional interpretation given on the right-hand side in **Definition A.2** are the same as those by Castagna and Xu [13]. They state that the empty type is interpreted as the empty set, the interpretation of the type variables is given by η , that unions and negations are interpreted as set-theoretic unions and complements, and that functions types are interpreted as sets of binary relations whose output is in the codomain if the input is in the domain.

The novelty of our definition is the interpretation of record types given on the left-hand side. There are two cases. The easy case is when the tail of the record type is either ϵ or \dots : in that case the interpretation of the record type is the set of all quasi constant functions in $\mathcal{L} \rightarrow \mathcal{P}(\mathcal{D}_\perp)$ that map a label ℓ into an element of the interpretation of $R(\ell)$ (recall that for $\ell \notin \text{lab}(R)$, $R(\ell)$ is \perp for $\text{tail}(R) = \epsilon$ and $\perp \vee \perp$ for $\text{tail}(R) = \dots$). If instead $\text{tail}(R)$ is a row variable ρ , then \mathcal{L} is partitioned in two, the sets $\text{lab}(R)$ and—by well-kindedness— $\text{def}(\rho)$, and the interpretation of R will be the set of quasi-constant functions in $\mathcal{L} \rightarrow \mathcal{D}_\perp$ obtained by unioning two partial functions: a function in $\prod_{\ell \in \text{lab}(R)} \llbracket R(\ell) \rrbracket_\eta^{\text{fld}}$ for the $\text{lab}(R)$ labels of \mathcal{L} , and a function in $\eta(\rho)$ for the remaining labels of \mathcal{L} . There is a caveat: fields can map labels both into values and \perp . Therefore, the interpretation of field-types must be slightly different from that of types, since it must map \perp into $\{\perp\}$ and the negation of a field-type is the complement with respect to \mathcal{D}_\perp , rather than \mathcal{D} : the $\llbracket \cdot \rrbracket^{\text{fld}}$ does just that.

Given a domain \mathcal{D} and a set-theoretic interpretation of the types into this domain, they form a *model* if the interpretation and the associated extensional interpretation have the same zeros:

DEFINITION A.3 (MODEL). *Let \mathcal{D} be a domain and $\llbracket \cdot \rrbracket : \mathcal{T} \rightarrow \mathcal{H} \rightarrow \mathcal{P}(\mathcal{D})$. The pair $(\mathcal{D}, \llbracket \cdot \rrbracket)$ is a model if and only, if for all $t \in \mathcal{T}$ and $\eta \in \mathcal{H}$, $\llbracket t \rrbracket_\eta = \emptyset \iff \mathbb{E}(t)_\eta = \emptyset$.*

Every model induces a subtyping relation on types¹⁴:

DEFINITION A.4 (SUBTYPING). *If $(\mathcal{D}, \llbracket \cdot \rrbracket)$ is a model, then it induces a subtyping relation defined as follows:*

$$t_1 \leq t_2 \stackrel{\text{def}}{\iff} \forall \eta. \llbracket t_1 \rrbracket_\eta \subseteq \llbracket t_2 \rrbracket_\eta$$

As explained by Frisch [20, Section 2.6], the interest of defining of a *model* is that we can work with the interpretation of the model “as if” the interpretation of the type constructors (in particular, the function type constructor) were defined as their extensional interpretation. So when deducing the properties for the subtyping relation of a model—and just for the subtyping relation—we can assume that $\mathcal{P}(\llbracket t_1 \rrbracket_\eta \times \llbracket t_2 \rrbracket_\eta)$, even if this is impossible for cardinality reasons.

Definition A.3 specifies which characteristics a model must have to induce a subtyping relation (that behaves “as if”), but it does not define any particular model nor, thus, any particular subtyping relation. In what follows we define a concrete interpretation domain \mathcal{D} (whose elements are defined by induction) and two specific interpretations, and prove that they satisfy the conditions to be models, since they both have the same zeros as the extensional interpretation (of one of them). This yields two equivalent definitions of a concrete subtyping relation we are going to use in the rest of this presentation. We will define:

- An interpretation $\llbracket t \rrbracket_\eta^q$ parametrized by an assignment η , for which subtyping $t_1 \leq^q t_2$ is defined as $\forall \eta. \llbracket t_1 \rrbracket_\eta^q \subseteq \llbracket t_2 \rrbracket_\eta^q$; (the index q stands for *quantified*, since subtyping is quantified on all variable interpretations);
- An interpretation of types directly into sets $\llbracket t \rrbracket$, that avoids quantification over η , and for which subtyping $t_1 \leq t_2$ is defined directly as $\llbracket t_1 \rrbracket \subseteq \llbracket t_2 \rrbracket$ (notice the absence of a variable interpretation argument η).

The interpretation of types is mutually recursive with interpretations of rows and field-types. Both of these will also give rise to subtyping relations. We will use the same notation \leq for the relations in $\mathcal{T} \times \mathcal{T}$, $\mathcal{T}_\perp \times \mathcal{T}_\perp$ and $\mathcal{R} \times \mathcal{R}$.

This interpretation in **Definition 2.5** induces a subtyping relation that it is easy to work with, since it got rid of the interpretation η for the variables. We can consider the interpretation $\llbracket \cdot \rrbracket : \mathcal{T} \rightarrow \mathcal{P}(\mathcal{D})$ as a function in $\mathcal{T} \rightarrow \mathcal{H} \rightarrow \mathcal{P}(\mathcal{D})$ that is constant on its second argument: if we apply

¹⁴Actually, a model must be convex: see Castagna and Xu [13]. We omit this detail since it is not relevant to our presentation.

Definition A.4 to it, then the subtyping relation is defined as simply as $t_1 \leq t_2 \stackrel{\text{def}}{\iff} \llbracket t_1 \rrbracket \subseteq \llbracket t_2 \rrbracket$. But getting rid of η makes it difficult to prove that this interpretation is a model and, thus, that when considering the properties of this subtyping relation, we can work “as if” the interpretation of type constructors were as in the extensional interpretation. To overcome this difficulty we define a second interpretation, on the same domain, but this interpretation disregards the indexes of the elements and uses an assignment η to interpret the variables.

DEFINITION A.5 (PARAMETRIZED INTERPRETATION OF TYPES AND ROWS). *We define a ternary predicate $(D : T)_\eta^q$ (“the element D belongs to T under assignment η ”), by induction on the pair (D, T) ordered lexicographically. The only differences with the predicate $(D : T)$ (apart from recursive calls to the appropriate predicate), are:*

$$(d : \alpha)_\eta^q = d \in \eta(\alpha)$$

$$(\delta : \theta)_\eta^q = \delta \in \eta(\theta)$$

$$\begin{aligned} (\llbracket \ell = \delta_\ell \rrbracket_{\ell \in L_1, -} = \perp^0 \Downarrow_{L_2}^V : r)_\eta^q &= (\forall \ell \in L_1. (\delta_\ell : r(\ell))_\eta^q) \text{ and } (\forall \ell \in \text{def}(r) \setminus L_1. (\perp^0 : r(\ell))_\eta^q) \\ &\text{and } \text{tail}(r) = \rho \implies \llbracket (\ell = \delta_\ell)_{\ell \in L_1 \cap \text{def}(\rho), -} = \perp^0 \Downarrow_{\mathcal{L} \setminus \text{def}(\rho)}^V \rrbracket \in \eta(\rho) \end{aligned}$$

We define the interpretations $\llbracket \cdot \rrbracket_\eta^q$, $\llbracket \cdot \rrbracket_\eta^{\text{fld}}$ and $\llbracket \cdot \rrbracket_\eta^{\text{grow}}$ as expected.

While the interpretation of type and field variables is straightforwardly given by η , the interpretation of row variables is less evident. The first line of the interpretation of a row is the same as in [Definition 2.5](#): in both definitions this line deals with the case when the tail of r is not a row variable. The second line covers the case for $\text{tail}(r) = \rho$: it checks that $\vec{d} \in \eta(\rho)$, where \vec{d} is obtained by restricting the quasi-constant function on the left to the definition space of ρ .

Our goal is to prove that both interpretations give a model of types. Formally, this corresponds to proving the following equivalences: Let $\mathbb{E}(\cdot)$ be the extensional interpretation of $\llbracket \cdot \rrbracket^q$. For all $t \in \mathcal{T}$:

$$(\forall \eta. \mathbb{E}(t)_\eta = \emptyset) \iff (\forall \eta. \llbracket t \rrbracket_\eta^q = \emptyset) \iff \llbracket t \rrbracket = \emptyset \quad (5)$$

The leftmost “iff” proves that $(\mathcal{D}, \llbracket \cdot \rrbracket^q)$ is a model, while the rightmost one proves that the subtyping relation induced by $\llbracket \cdot \rrbracket$ is the same as the one induced by the model $\llbracket \cdot \rrbracket^q$ (since $\forall \eta. \llbracket s \rrbracket_\eta^q \subseteq \llbracket t \rrbracket_\eta^q \iff \forall \eta. \llbracket s \rrbracket_\eta^q \cap (\mathcal{D} \setminus \llbracket t \rrbracket_\eta^q) = \emptyset \iff \forall \eta. \llbracket s \wedge \neg t \rrbracket_\eta^q = \emptyset \iff \llbracket s \wedge \neg t \rrbracket = \emptyset \iff \llbracket s \rrbracket \subseteq \llbracket t \rrbracket$).

For the first equivalence, we prove the following, more precise, statement.

LEMMA A.1. *For all type t , for all η ,*

$$\llbracket t \rrbracket_\eta^q = \emptyset \iff \mathbb{E}(t)_\eta = \emptyset$$

PROOF. For all d , we show $(d : t)_\eta^q \iff d \in \mathbb{E}(t)_\eta$ by induction on t in both directions. This induction is well-founded because the cases for type constructors do not use induction, $\mathbb{E}(t)_\eta$ is defined on top of $\llbracket t \rrbracket_\eta^q$, and the number of type connectives is finite by regularity of the types.

We start with the left-to-right implication and detail the case $t = R$. By hypothesis there is $\vec{d} = \llbracket (\ell = \delta_\ell)_{\ell \in L, -} = \perp^0 \Downarrow_0^V \rrbracket$ such that $(\text{Rec}(\vec{d})^{V'} : R)_\eta^q$. By hypothesis, $\forall \ell \in L. (\delta_\ell : R(\ell))_\eta^q$, so $\delta_\ell \in \llbracket R(\ell) \rrbracket_\eta^{\text{fld}}$, and $\forall \ell \in \mathcal{L} \setminus L. (\perp^0 : R(\ell))_\eta^q$, so $\perp^0 \in \llbracket R(\ell) \rrbracket_\eta^{\text{fld}}$. It is easy to see that this implies respectively $\delta_\ell \in \llbracket R(\ell) \rrbracket_\eta^{\text{fld}}$ and $\perp^0 \in \llbracket R(\ell) \rrbracket_\eta^{\text{fld}}$. Moreover, if $\text{tail}(\rho) = \rho$, then $\llbracket (\ell = \delta_\ell)_{\ell \in L \cap \text{def}(\rho), -} = \perp^0 \Downarrow_{\mathcal{L} \setminus \text{def}(\rho)}^V \rrbracket \in \eta(\rho)$. So $\vec{d} \in \mathbb{E}_\eta(R)$.

Now, for the right-to-left implication. Let $\vec{d} = \llbracket (\ell = \delta_\ell)_{\ell \in L, -} = \perp^0 \Downarrow_0^V \rrbracket \in \mathbb{E}_\eta(R)$. For all $\ell \in \text{lab}(R)$, we have by hypothesis $\delta \in \llbracket R(\ell) \rrbracket_\eta^{\text{fld}}$, which implies $(\delta : R(\ell))_\eta^{\text{fld}}$. Let $\ell \notin \text{lab}(R)$. If $\ell \in L_1$, then $(\delta_\ell : R(\ell))_\eta^q$ holds. If $\ell \notin L_1$: if $\text{tail}(R) \in \mathcal{V}$, by definition $R(\ell) = \mathbb{1} \vee \perp$, and if $\text{tail}(R) \notin \mathcal{V}$, $R(\ell) = \mathbb{1} \vee \perp$, or $R(\ell) = \perp$. In any case, $(\perp^0 : R(\ell))_\eta^q$ holds. Finally, if $\text{tail}(R) = \rho \in \mathcal{V}$, then $\llbracket (\ell = \delta_\ell)_{\ell \in L \cap \text{def}(\rho), -} = \perp^0 \Downarrow_{\mathcal{L} \setminus \text{def}(\rho)}^V \rrbracket \in \eta(\rho)$. \square

We have thus shown that the subtyping relation generated by $\llbracket \cdot \rrbracket^q$ has the expected properties described by $\mathbb{E}(\cdot)$. In particular, it is a *set-theoretic* model because type operators are interpreted as set operators.

Since it will be easier to work directly with interpretations as sets rather than to quantify over η , we now show that the subtyping relation generated by $\llbracket \cdot \rrbracket$ is equivalent to the parametrized one. We show that equivalence not only on types, but also on field-types and rows. The main element of the proof is the canonical assignment $\hat{\eta}$, defined as

$$\hat{\eta}(\alpha) = \{d \in \mathcal{D} \mid \alpha \in \text{tag}(d)\} \quad (6)$$

$$\hat{\eta}(\theta) = \{\delta \in \mathcal{D}_\perp \mid \theta \in \text{tag}(\delta)\} \quad (7)$$

$$\hat{\eta}(\rho) = \{\check{d} \in \mathcal{D}_{\text{row}} \mid \text{def}(\check{d}) = \text{def}(\rho) \text{ and } \rho \in \text{tag}(\check{d})\} \quad (8)$$

LEMMA A.2. For every $T \in \mathcal{T}_\perp \cup \mathcal{R}$, $\llbracket T \rrbracket = \llbracket T \rrbracket_{\hat{\eta}}^q$.

PROOF. For any D and T we prove that $(D : T) \iff (D : T)_{\hat{\eta}}^q$ by induction on (D, T) . The only interesting case is when $T = r$ and $D = \langle (\ell = \delta_\ell)_{\ell \in L_1}, _ = \perp^0 \rangle_{L_2}^V$. For all $\ell \in L_1$ we have $(\delta_\ell : r(\ell)) \iff (\delta_\ell : r(\ell))_{\hat{\eta}}^q$ by induction hypothesis. Let $\ell \notin L_1$. We show that $(\perp^0 : r(\ell)) \iff (\perp^0 : r(\ell))_{\hat{\eta}}^q$ by induction on $r(\ell)$. This induction is well-founded : for $r(\ell) = \perp$, both propositions are true and they are false for any other type constructor (in particular $r(\ell) = \theta$). The inductive cases on type operators are straightforward. If $\text{tail}(r) \notin \mathcal{V}$, we are done. Otherwise, let $\text{tail}(r) = \rho$. On the left side, we have $\rho \in V$. On the right side, we have $\langle (\ell = \delta_\ell)_{\ell \in L \cap \text{def}(\rho)}, _ = \perp^0 \rangle_{L \setminus \text{def}(\rho)}^V \in \hat{\eta}(\rho)$. By definition of $\hat{\eta}(\rho)$, this is equivalent to $\rho \in V$. \square

LEMMA A.3. Let $W \in \mathcal{P}_{\text{fin}}(\mathcal{V})$ and $T_W = \{T \in \mathcal{T}_\perp \cup \mathcal{R} \mid \text{vars}(T) \subseteq W\}$. For every $T \in T_W$,

$$\llbracket T \rrbracket_{\hat{\eta}}^q = \emptyset \iff \forall \eta. \llbracket T \rrbracket_{\eta}^q = \emptyset.$$

PROOF. The right-to-left implication is trivial, by instantiation of the quantifier by η' . The left-to-right implication is by contraposition: for an arbitrary W and T_W , we prove $\forall T \in T_W. (\exists \eta. \llbracket T \rrbracket_{\eta}^q \neq \emptyset \implies \llbracket T \rrbracket_{\hat{\eta}}^q \neq \emptyset)$. For this, we define the functions $F_W^\eta : \mathcal{D}_\perp \cup \mathcal{D}_{\text{row}} \cup \{\Omega\} \rightarrow \mathcal{D}_\perp \cup \mathcal{D}_{\text{row}} \cup \{\Omega\}$ as $F_W^\eta(\Omega) = \Omega$ and:

$$F_W^\eta(D) = \begin{cases} c^{\hat{V}(D)} & \text{if } D = c; \\ \{(F_W^\eta(d_1), F_W^\eta(\partial_1)), \dots, (F_W^\eta(d_n), F_W^\eta(\partial_n))\}^{\hat{V}(D)} & \text{if } D = \{(d_1, \partial_1), \dots, (d_n, \partial_n)\}^V; \\ \text{Rec}(\check{d})^{\hat{V}(D)} & \text{if } D = \text{Rec}(\check{d})^V; \\ \perp^{\hat{V}(D)} & \text{if } D = \perp^V; \\ \langle (\ell = F_W^\eta(\delta_\ell))_{\ell \in L_1}, _ = \perp^0 \rangle_{L_2}^{\hat{V}(D)} & \text{if } D = \langle (\ell = \delta_\ell)_{\ell \in L_1}, _ = \perp^0 \rangle_{L_2}^V \end{cases}$$

where $\hat{V}(D) = \{\alpha \in W \mid D \in \eta(\alpha)\} \cup \{\theta \in W \mid D \in \eta(\theta)\} \cup \{\rho \in W \mid D \in \eta(\rho)\}$. The finiteness of W ensures that \hat{V} is finite. We prove the following statement, for an arbitrary η and by induction on (D, T) ordered lexicographically:

$$\forall T \in T_W. \forall D \in \mathcal{D}_\perp \cup \mathcal{R}. (D : T)_{\hat{\eta}}^q \implies (F_W^\eta(D) : T)_{\hat{\eta}}^q$$

- $T = \alpha$. We have $(F_W^\eta(D) : \alpha)_{\hat{\eta}}^q \iff \alpha \in \text{tag}(F_W^\eta(D)) \iff \alpha \in \hat{V}(D) \iff D \in \eta(\alpha)$ and $\alpha \in W \iff (D : \alpha)_{\hat{\eta}}^q$. The last equivalence holds by the hypothesis that $T \in T_W$. The case for $T = \theta$ is similar.
- $T = \perp$ and $D = \perp^V$. $(F_W^\eta(\perp^V) : \perp)_{\hat{\eta}}^q = (\perp^{\hat{V}(D)} : \perp)_{\hat{\eta}}^q$ holds.

- $T = R$ and $D = \text{Rec}(\vec{d})^V$. By hypothesis, we have $(\vec{d} : \text{row}(R))_{\eta}^q$. By induction, this implies $(F_W^{\eta}(\vec{d}) : \text{row}(R))_{\eta}^q$ and thus $(F_W^{\eta}(D) : R)_{\eta}^q$.
- $d = \langle (\ell = \delta_{\ell})_{\ell \in L_1}, _ = \perp^0 \rangle_{L_2}^V$ and $t = r$. The statement holds for labels in and outside of L_1 by induction hypothesis. If $\text{tail}(r) \notin \mathcal{V}$, we are done. Let $\text{tail}(r) = \rho$. By hypothesis, $\rho \in W$. By definition of the predicate, there is $\vec{d} = \langle (\ell = \delta_{\ell})_{\ell \in L_1 \cap \text{def}(\rho)}, _ = \perp^0 \rangle_{L \setminus \text{def}(\rho)}^V \in \eta(\rho)$. As in the case for type variables, we show: $(F_W^{\eta}(\vec{d}) : \rho)_{\eta}^q \iff \rho \in \text{tag}(F_W^{\eta}(\vec{d})) \iff \rho \in \hat{V}(\vec{d}) \iff D \in \eta(\rho)$ and $\rho \in W$.
- Other cases can be found in [39, Lemma 2.8] or are direct by falsity of the premise. \square

LEMMA A.4. For all t_1 and t_2 , $t_1 \leq^q t_2 \iff t_1 \leq t_2$.

PROOF. By definition, Lemma A.3 and Lemma A.2, we show:

$$t_1 \leq^q t_2 \iff \forall \eta. \llbracket t_1 \setminus t_2 \rrbracket_{\eta}^q = \emptyset \iff \llbracket t_1 \setminus t_2 \rrbracket_{\eta}^q = \emptyset \iff \llbracket t_1 \setminus t_2 \rrbracket = \emptyset \iff t_1 \leq t_2 \quad \square$$

A.4 Subtyping Relation

LEMMA A.5. Let r be an atomic row of definition space $\mathcal{L} \setminus L_r$ and L such that $\text{lab}(r) \subseteq L \subseteq \text{def}(r)$. Then,

$$r \simeq \langle (\ell = r(\ell) | _)_{\ell \in L} \rangle^{L_r} \wedge \langle L' | \text{tail}(r) \rangle^{L_r} \simeq \bigwedge_{\ell \in L} \langle \ell = r(\ell) | _ \rangle^{L_r} \wedge \langle L' | \text{tail}(r) \rangle^{L_r}$$

where $L' = \text{lab}(r)$ if $\text{tail}(r) \in \mathcal{V}$ and $L' = L$ otherwise.

PROOF. Straightforward by the definition of the models. \square

The function Φ we define in Section 2.3 to decide subtyping crucially relies on the formula we give in Lemma A.6. It gives a characterization of the emptiness of $\bigwedge_{r \in P} r \wedge \bigwedge_{r \in N} \neg r$. While function Φ is stated on records, we prefer to state this lemma on rows, as we will refer back to it in that way for tallying (Appendix C). The corollary for records follows immediately by $t_1 \leq t_2 \iff \text{row}(t_1) \leq \text{row}(t_2)$ when $t_1, t_2 \leq \{_ | _ \}$. This lemma generalizes to rows and polymorphic record types the decomposition of monomorphic ones defined by Frisch [20]. The main difference is the addition the third condition on line (11), that checks whether a row variable appears both in the positive and in the negative fragment.

LEMMA A.6. Let P and N be sets of atomic row types r each of definition space $\mathcal{L} \setminus L_r$. Let L be a finite set of labels such that $\bigcup_{r \in P \cup N} \text{lab}(r) \subseteq L \subseteq \mathcal{L} \setminus L_r$. Let $P_{\mathcal{V}} = \{r \in P \mid \text{tail}(r) \in \mathcal{V}\}$ and likewise for $N_{\mathcal{V}}$. For every r , we define its default type $\text{def}(r)$ as: $\text{def}(r) = \perp$ if r is closed, and $\text{def}(r) = \perp \vee \perp$ otherwise. The relation $\bigwedge_{r \in P} r \leq \bigvee_{r \in N} r$ holds iff $\forall \iota : N \rightarrow L \cup \{_ \}$,

$$\left(\exists \ell \in L. \bigwedge_{r \in P} r(\ell) \leq \bigvee_{r \in \iota^{-1}(\ell)} r(\ell) \right) \quad (9)$$

$$\text{or } \left(\exists r_o \in \iota^{-1}(_) \setminus N_{\mathcal{V}}. \left(\bigwedge_{r \in P} \text{def}(r) \leq \text{def}(r_o) \right) \right) \quad (10)$$

$$\text{or } \left(\exists r_o \in \iota^{-1}(_) \cap N_{\mathcal{V}}. \exists r \in P_{\mathcal{V}}. \text{tail}(r_o) = \text{tail}(r) \right) \quad (11)$$

PROOF. In the following, we let $L_i = \text{lab}(r_i)$ and $\zeta_i = \text{tail}(r_i)$. Using Lemma A.5, we decompose the conjunction into:

$$\bigwedge_{r_p \in P} \left(\langle (\ell = r_p(\ell))_{\ell \in L} | _ \rangle^{L_r} \wedge \langle L'_p | \zeta_p \rangle^{L_r} \right) \wedge \bigwedge_{r_n \in N} \left(\bigvee_{\ell \in L} \langle \ell = \neg r_n(\ell) | _ \rangle^{L_r} \vee \neg \langle L'_n | \zeta_n \rangle^{L_r} \right) \quad (12)$$

Where $L'_i = L_i$ if $r_i \in \mathcal{V}$ and $L'_i = L$ otherwise. We can distribute the intersection of the elements of N on the right of (12) over the unions in the second brackets. We obtain a union of intersections of, each time, $|N|$ elements, where each intersection is a possible combination of the individual rows present in the second line. Each combination is described by a function $\iota : N \rightarrow L \cup \{_ \}$, where $\iota(r_n) = \ell$ means that the element $\langle \ell = \neg r_n(\ell) | _ \rangle^{L_r}$ is present in the combination given by ι , while $\iota(r_n) = _$ means that the element $\neg \langle L'_n | \zeta_n \rangle^{L_r}$ is present in the combination. For each $r_n \in N$, let us write $r_\ell^n = \langle \ell = \neg r_n(\ell) | _ \rangle^{L_r}$ and $r_-^n = \neg \langle L'_n | \zeta_n \rangle^{L_r}$. Therefore the row in (12) is equivalent to:

$$\bigwedge_{r_p \in P} (\langle (\ell = r_p(\ell))_{\ell \in L} | _ \rangle^{L_r} \wedge \langle L'_p | \zeta_p \rangle^{L_r}) \wedge \bigvee_{\iota : N \rightarrow L \cup \{_ \}} \left(\bigwedge_{r_n \in N} r_{\iota(r_n)}^n \right) \quad (13)$$

By distributing the intersection over the union we obtain

$$\bigvee_{\iota : N \rightarrow L \cup \{_ \}} \left(\bigwedge_{r_p \in P} (\langle (\ell = r_p(\ell))_{\ell \in L} | _ \rangle^{L_r} \wedge \langle L'_p | \zeta_p \rangle^{L_r}) \wedge \bigwedge_{r_n \in N} r_{\iota(r_n)}^n \right) \quad (14)$$

A union is empty if and only if each summand of the union is empty. Therefore the row above is empty if and only if for all $\iota : N \rightarrow L \cup \{_ \}$, the following is empty:

$$\begin{aligned} & \bigwedge_{r_p \in P} (\langle (\ell = r_p(\ell))_{\ell \in L} | _ \rangle^{L_r} \wedge \langle L'_p | \zeta_p \rangle^{L_r}) \wedge \bigwedge_{r_n \in N} r_{\iota(r_n)}^n \\ & \simeq \bigwedge_{r_p \in P} (\langle (\ell = r_p(\ell))_{\ell \in L} | _ \rangle^{L_r} \wedge \langle L'_p | \zeta_p \rangle^{L_r}) \wedge \bigwedge_{\ell \in L \cup \{_ \}} \bigwedge_{r_n \in \iota^{-1}(\ell)} r_\ell^n \\ & \simeq \bigwedge_{r_p \in P} (\langle (\ell = r_p(\ell))_{\ell \in L} | _ \rangle^{L_r} \wedge \langle L'_p | \zeta_p \rangle^{L_r}) \wedge \bigwedge_{r_n \in \iota^{-1}(_)} r_-^n \wedge \bigwedge_{\ell \in L} \bigwedge_{r_n \in \iota^{-1}(\ell)} r_\ell^n \\ & = \bigwedge_{r_p \in P} (\langle (\ell = r_p(\ell))_{\ell \in L} | _ \rangle^{L_r} \wedge \langle L'_p | \zeta_p \rangle^{L_r}) \wedge \bigwedge_{r_n \in \iota^{-1}(_)} \neg \langle L'_n | \zeta_n \rangle^{L_r} \wedge \bigwedge_{\ell \in L} \bigwedge_{r_n \in \iota^{-1}(\ell)} \langle \ell = \neg r_n(\ell) | _ \rangle^{L_r} \\ & \simeq \bigwedge_{r_p \in P} (\langle (\ell = r_p(\ell))_{\ell \in L} | _ \rangle^{L_r} \wedge \langle L'_p | \zeta_p \rangle^{L_r}) \wedge \bigwedge_{r_n \in \iota^{-1}(_)} \neg \langle L'_n | \zeta_n \rangle^{L_r} \wedge \langle (\ell = \bigwedge_{r_n \in \iota^{-1}(\ell)} \neg r_n(\ell))_{\ell \in L} | _ \rangle^{L_r} \\ & \simeq \langle (\ell = \bigwedge_{r_p \in P} r_p(\ell) \wedge \bigwedge_{r_n \in \iota^{-1}(\ell)} \neg r_n(\ell))_{\ell \in L} | _ \rangle^{L_r} \wedge \bigwedge_{r_p \in P} \langle L'_p | \zeta_p \rangle^{L_r} \wedge \bigwedge_{r_n \in \iota^{-1}(_)} \neg \langle L'_n | \zeta_n \rangle^{L_r} \\ & \simeq \langle (\ell = \bigwedge_{r_p \in P} r_p(\ell) \wedge \bigwedge_{r_n \in \iota^{-1}(\ell)} \neg r_n(\ell))_{\ell \in L} | _ \rangle^{L_r} \\ & \wedge \bigwedge_{r_p \in P_{\bar{\mathcal{V}}}} \langle L | \zeta_p \rangle^{L_r} \wedge \bigwedge_{r_n \in \iota^{-1}(_) \cap N_{\bar{\mathcal{V}}}} \neg \langle L | \zeta_n \rangle^{L_r} \wedge \bigwedge_{r_p \in P_{\mathcal{V}}} \langle L_p | \zeta_p \rangle^{L_r} \wedge \bigwedge_{r_n \in \iota^{-1}(_) \cap N_{\mathcal{V}}} \neg \langle L_n | \zeta_n \rangle^{L_r} \end{aligned}$$

Let:

- $r_i^1 = \langle (\ell = \bigwedge_{r_p \in P} r_p(\ell) \wedge \bigwedge_{r_n \in \iota^{-1}(\ell)} \neg r_n(\ell))_{\ell \in L} | _ \rangle^{L_r}$;
- $r_i^2 = \bigwedge_{r_p \in P_{\bar{\mathcal{V}}}} \langle L | \zeta_p \rangle^{L_r} \wedge \bigwedge_{r_n \in \iota^{-1}(_) \cap N_{\bar{\mathcal{V}}}} \neg \langle L | \zeta_n \rangle^{L_r}$;
- $r_i^3 = \bigwedge_{r_p \in P_{\mathcal{V}}} \langle L_p | \zeta_p \rangle^{L_r} \wedge \bigwedge_{r_n \in \iota^{-1}(_) \cap N_{\mathcal{V}}} \neg \langle L_n | \zeta_n \rangle^{L_r}$.

We can see that r_i^1 is empty *iff* condition (9) holds, r_i^2 is empty *iff* condition (10) does (in the case where $P_{\bar{\mathcal{V}}}$ is empty, notice that the intersection is equal to $\mathbb{1} \vee \perp$), and r_i^3 is empty *iff* condition (11) holds. We directly obtain that if one of the conditions holds, then the row r_i is empty. We now show that if r_i is empty, then there is $1 \leq i \leq 3$ such that r_i^i is empty.

For this, we suppose that none of the subtypes is empty and build an element $\vec{d} \in \llbracket r_i \rrbracket^{\text{row}}$.

(1) Since r_i^1 is not empty, for all $\ell \in L$ there is an element $\delta_\ell^1 \in \llbracket \bigwedge_{r_p \in P} r_p(\ell) \wedge \bigwedge_{r_n \in \iota^{-1}(\ell)} \neg r_n(\ell) \rrbracket^{\text{fld}}$.

- (2) Since r_i^2 is not empty, there is an element $\langle (\ell = \delta_\ell^2)_{\ell \in L_2, -} = \perp^0 \rangle^{V_2} \in \llbracket r_i^2 \rrbracket^{\text{row}}$.
- (3) Since r_i^3 is not empty, there is an element $\hat{d}_3 \in \llbracket r_i^3 \rrbracket^{\text{row}}$. However, the restrictions on the set of elements in $\llbracket r_i^3 \rrbracket^{\text{row}}$ only concern their tags so that any element \hat{d}' with $\text{tag}(\hat{d}') = \text{tag}(\hat{d}_3)$ and $\text{def}(\hat{d}') = \text{def}(\hat{d}_3)$ is in $\llbracket r_3 \rrbracket^{\text{row}}$. Let $V_3 = \text{tag}(\hat{d}_3)$.

We build the element $\langle (\ell = \delta_\ell^1)_{\ell \in L}, (\ell = \delta_\ell^2)_{\ell \in L_2 \setminus L, -} = \perp^0 \rangle^{V_3}$. This element belongs to $\llbracket r_i \rrbracket^{\text{row}}$, which is a contradiction. \square

A.5 Subtyping Algorithm

Naively implementing the above subtyping formula requires backtracking. Indeed, for all map $\iota : N \rightarrow L \cup \{_ \}$, we have to check if subtyping holds on one of the labels $\ell \in L$. On that recursive call, since the types are coinductive, we need to assume that the type we are checking is empty. So, we are collecting a series of emptiness assumptions along the call stack. If later a contradiction arises, we need to backtrack to the point where the wrong assumption was introduced, to then take another branch, in our case, check subtyping for another ℓ . Our function Φ avoids backtracking to compute subtyping more efficiently, following [20, Chapter 7].

LEMMA 2.3 (SOUNDNESS AND COMPLETENESS OF Φ). *Let R_o be a monomorphic record type, $V_p \subset \mathcal{V}_r$ finite and N a finite set of (polymorphic) atomic record types. Then,*

$$R_o \wedge \bigwedge_{\rho \in V_p} \{\mathcal{L} \setminus \text{def}(\rho) \mid \rho\} \leq \bigvee_{R \in N} R \iff R_o \leq \emptyset \text{ or } \Phi(R_o, V_p, N).$$

PROOF. If $R_o \simeq \emptyset$, the result holds. Otherwise, we prove this by induction on the cardinality of N . In the following, given a variable $\rho \in V_p$, let us write L_ρ for $\mathcal{L} \setminus \text{def}(\rho)$.

If $N = \emptyset$, the union $\bigvee_{R \in N} R$ is empty. So the statement holds if and only if $R_o \simeq \emptyset$, since $\Phi(R_o, V_p, \emptyset) = \text{false}$, and $\bigwedge_{\rho \in V_p} \{L_\rho \mid \rho\}$ is never empty.

Now, let $N = N' \cup \{R\}$. Let $L = \text{lab}(R_o)$. R can be decomposed as $\bigwedge_{\ell \in L} \{\ell = R(\ell) \mid \dots\} \wedge \{L' \mid \zeta\}$, where $L' = L$ if $\zeta \notin \mathcal{V}$ and $L' = \text{lab}(R)$ otherwise. The left-hand side of the statement is thus equivalent to $R_o \wedge \bigwedge_{\rho \in V_p} \{L_\rho \mid \rho\} \wedge (\bigvee_{\ell \in L} \{\ell = \neg R(\ell) \mid \dots\} \vee \neg\{L' \mid \zeta\}) \leq \bigvee_{n \in N'} R_n$. We can distribute the intersection over the unions. We must then prove an equivalence between $(R_o \simeq \emptyset \text{ or } \Phi(R_o, V_p, N))$ and:

$$\forall \ell \in L. R_o \wedge \{\ell = \neg R(\ell) \mid \dots\} \wedge \bigwedge_{\rho \in V_p} \{L_\rho \mid \rho\} \leq \bigvee_{n \in N'} R_n \quad (15)$$

$$\text{and } R_o \wedge \bigwedge_{\rho \in V_p} \{L_\rho \mid \rho\} \wedge \neg\{L' \mid \zeta\} \leq \bigvee_{n \in N'} R_n \quad (16)$$

We now have to verify that each of these statements are equivalent to $\Phi(R_o, V_p, N)$.

We start with (15). Let $\ell \in L$ and let $R_o^\ell = R_o \wedge \{\ell = \neg R(\ell) \mid \dots\}$. By the induction hypothesis, we have that $R_o^\ell \wedge \bigwedge_{\rho \in V_p} \{L_\rho \mid \rho\} \leq \bigvee_{n \in N'} R_n \iff R_o^\ell \simeq \emptyset \text{ or } \Phi(R_o^\ell, V_p, N')$. Since $R_o \neq \emptyset$, $R_o^\ell \simeq \emptyset \iff R_o(\ell) \leq R(\ell)$.

We continue with (16). We define $\Psi(R_o, V_p, \{L' \mid \zeta\})$ as $(\zeta = \dots \text{ or } \zeta = \text{tail}(R_o) \text{ or } \zeta \in V_p)$. We show that (16) is equivalent to: $\Psi(R_o, V_p, \{L' \mid \zeta\})$ or $(\neg\Psi(R_o, V_p, \{L' \mid \zeta\}) \text{ and } \Phi(R_o, V_p, N'))$. It is easy to show using Lemma A.6 that $R_o \wedge \bigwedge_{\rho \in V_p} \{L_\rho \mid \rho\} \wedge \neg\{L' \mid \zeta\}$ is empty iff $\Psi(R_o, V_p, \{L' \mid \zeta\})$ holds. In particular, the first condition of Lemma A.6 never holds since $L' = L$ when $\zeta \notin \mathcal{V}$. Then, there are two cases.

- (1) $R_o \wedge \bigwedge_{\rho \in V_p} \{L_\rho \mid \rho\} \wedge \neg\{L' \mid \zeta\} \leq \emptyset$. This means that $\Psi(R_o, V_p, \{L' \mid \zeta\})$ holds, and also that $R_o \wedge \bigwedge_{\rho \in V_p} \{L_\rho \mid \rho\} \wedge \neg\{L' \mid \zeta\} \leq \bigvee_{n \in N'} R_n$.

- (2) $R_o \wedge \bigwedge_{\rho \in V_p} \{L_\rho \mid \rho\} \wedge \neg\{L' \mid \zeta\} \not\leq 0$. This means that $\Psi(R_o, V_p, \{L' \mid \zeta\})$ does not hold. Thus, there are two possible cases: either (a) $\text{tail}(R_o) = \epsilon$ and $\zeta = \dots$, or (b) $\zeta = \rho \notin V_p$. We show that $R_o \wedge \bigwedge_{\rho \in V_p} \{L_\rho \mid \rho\} \wedge \neg\{L' \mid \zeta\} \leq \bigvee_{R \in N'} R$ is equivalent to $R_o \wedge \bigwedge_{\rho \in V_p} \{L_\rho \mid \rho\} \leq \bigvee_{R \in N'} R$. From this, we use the induction hypothesis to obtain the equivalence with $\Phi(R_o, V_p, N')$ (since $R_o \neq 0$).

The right-to-left implication of the equivalence is trivial. For the converse implication, we use [Lemma A.6](#) on $R_o \wedge \bigwedge_{\rho \in V_p} \{L_\rho \mid \rho\} \leq \neg\{L' \mid \zeta\} \vee \bigvee_{R \in N'} R$. By the hypothesis (a) and (b) in the corresponding cases, the second and third conditions of that lemma never hold. Thus, we have by hypothesis that $\forall l : N' \cup \{L' \mid \zeta\} \rightarrow L \cup \{_\} . \exists \ell \in L . R_o(\ell) \leq \bigvee_{R \in \ell^{-1}(\ell)} R(\ell)$. The implication holds because $\forall \ell \in L . \{L' \mid \zeta\}(\ell) = \perp \vee \perp$.

Summing up, we have proved by induction that if $R_o \wedge \bigwedge_{\rho \in V_p} \{L_\rho \mid \rho\}$ is not empty, checking that it is a subtype of $\bigvee_{n \in N} R_n$ is equivalent to checking both these two propositions:

- (1) $\forall \ell \in L . ((R_o(\ell) \leq R(\ell)) \text{ or } \Phi(R_o \wedge \{\ell = \neg R(\ell) \mid \dots\}, V_p, N'))$
- (2) $(\Psi(R_o, V_p, \{L' \mid \zeta\})) \text{ or } (\neg\Psi(R_o, V_p, \{L' \mid \zeta\}) \text{ and } \Phi(R_o, V_p, N'))$

To conclude, notice that if $(\neg\Psi(R_o, V_p, \{L' \mid \zeta\}) \text{ and } \Phi(R_o, V_p, N'))$ holds, then by induction hypothesis we have $R_o \wedge \bigwedge_{\rho \in V_p} \{L_\rho \mid \rho\} \leq \bigvee_{n \in N'} R_n$ and, *a fortiori*, $R_o \wedge \bigwedge_{\rho \in V_p} \{L_\rho \mid \rho\} \leq R \vee \bigvee_{n \in N'} R_n$. It is therefore useless to check the other proposition (1) above, which thus must be checked only when $\Psi(R_o, V_p, \{L' \mid \zeta\})$ holds. This yields

$$\begin{aligned} & (\neg\Psi(R_o, V_p, \{L' \mid \zeta\}) \text{ and } \Phi(R_o, V_p, N')) \\ & \text{or } (\Psi(R_o, V_p, \{L' \mid \zeta\}) \text{ and } (\forall \ell \in L . (R_o(\ell) \leq R(\ell)) \text{ or } \Phi(R_o \wedge \{\ell = \neg R(\ell) \mid \dots\}, V_p, N'))) \end{aligned}$$

which corresponds to the second clause of the definition of Φ . \square

PROPOSITION 2.4. *The subtyping algorithm terminates. As a corollary, subtyping is decidable.*

PROOF. The number of disjoint types in a DNF is finite. Also, the preprocessing of a conjunction of record types can be defined for all such types and computed in a finite number of steps. Finally, in function Φ , the number of elements in the third parameter decreases at each recursive call. Moreover, the subtyping relation on non-record types is decidable [13], from which we get decidability of the subtyping relation on field-types. \square

A.6 Substitutions

LEMMA A.7. *Let $\llbracket \cdot \rrbracket_\eta^q$ be the appropriate interpretation among $\llbracket \cdot \rrbracket_\eta^q$, $\llbracket \cdot \rrbracket_\eta^{\text{fld}}$ and $\llbracket \cdot \rrbracket_\eta^{\text{row}}$. For every T , σ and η , if η' is defined by $\eta'(X) = \llbracket \sigma(X) \rrbracket_{\eta'}^q$, then $\llbracket T\sigma \rrbracket_\eta^q = \llbracket T \rrbracket_{\eta'}^q$.*

PROOF. For an arbitrary σ and η , we show that

$$\forall T \in \mathcal{T}_\perp \cup \mathcal{R} . \forall D \in \mathcal{D}_\perp \cup \mathcal{D}_{\text{row}} . (D : T\sigma)_\eta^q \iff (D : T)_{\eta'}^q$$

by induction on (D, T) and with η' defined as before. We detail two cases, the others are straightforward.

- $T = \alpha$ and $D = d$. On the left, we have $(d : \alpha\sigma)_\eta^q = (d : \sigma(\alpha))_\eta^q$ and on the right $(d : \alpha)_{\eta'}^q = d \in \eta'(\alpha) = d \in \llbracket \sigma(\alpha) \rrbracket_{\eta'}^q = (d : \sigma(\alpha))_\eta^q$.
- $T = \{(\ell = \tau_\ell)_{\ell \in L} \mid \rho\}$ and $D = \text{Rec } \Downarrow(\ell = \delta_\ell)_{\ell \in L_d, _} = \perp^0 \Downarrow^V$. The case for rows is similar. We have $T\sigma = \{(\ell = \tau_\ell)_{\ell \in L} \mid \dots\} \wedge \{L \mid \sigma(\rho)\}$. Let $\vec{d} = \Downarrow(\ell = \delta_\ell)_{\ell \in L_d \wedge L, _} = \perp^0 \Downarrow_L^V$. On the left, we have:

$$(D : T\sigma)_\eta^q = (\forall \ell \in L_d . (\delta_\ell : T(\ell)\sigma)_\eta^q) \text{ and } (\forall \ell \notin L_d . (\perp^0 : T(\ell)\sigma)_\eta^q \text{ and } (\vec{d} : \sigma(\rho))_\eta^q)$$

By induction hypothesis, the first two conditions are equivalent to $\forall \ell \in L_d. (\delta_\ell : T(\ell))_{\eta'}^q$ and $\forall \ell \notin L_d. (\perp^0 : T(\ell))_{\eta'}^q$. By the same reasoning as in the previous case, the last condition is equivalent to $(\vec{d} : \rho)_{\eta'}^q$, which altogether give $(D : T)_{\eta'}^q$. \square

PROPOSITION 2.5. *If $t_1 \leq t_2$, then $t_1\sigma \leq t_2\sigma$ for any row substitution σ .*

PROOF. By definition, $t_1 \leq t_2 \iff \llbracket t_1 \setminus t_2 \rrbracket = \emptyset$. By [Lemma A.4](#), this is equivalent to $\forall \eta. \llbracket t_1 \setminus t_2 \rrbracket_{\eta'}^q$. In particular, this holds for η' defined as in [Lemma A.7](#), so that $\llbracket t_1 \setminus t_2 \rrbracket_{\eta'}^q = \emptyset$. By [Lemma A.7](#), this implies $\llbracket (t_1 \setminus t_2)\sigma \rrbracket_{\eta'}^q = \emptyset$ which means $t_1\sigma \leq t_2\sigma$. \square

B APPENDIX FOR LANGUAGE

B.1 Syntax and Semantics

DEFINITION B.1 (TOP-LEVEL VARIABLES). *The top-level variables of a type (resp. field-type, row) are defined as $\text{tlv}(t) = \text{tlv}'(t) \cap \mathcal{V}_t$ (resp. $\text{tlv}(\tau) = \text{tlv}'(\tau) \cap \mathcal{V}_f$, $\text{tlv}(r) = \text{tlv}'(r) \cap \mathcal{V}_r$).*

$$\begin{aligned} \text{tlv}'(\alpha) &= \{\alpha\} \\ \text{tlv}'(\theta) &= \{\theta\} \\ \text{tlv}'(\langle \ell = \tau, \dots, \ell = \tau \mid \rho \rangle^L) &= \text{tlv}'(\{\ell = \tau, \dots, \ell = \tau \mid \rho\}) = \{\rho\} \\ \text{tlv}'(T_1 \vee T_2) &= \text{tlv}'(T_1) \cup \text{tlv}'(T_2) \\ \text{tlv}'(\neg T) &= \text{tlv}'(T) \\ \text{tlv}'(T) &= \emptyset \qquad \text{otherwise} \end{aligned}$$

DEFINITION B.2. *Given a type term T , we write $\text{vars}(T)$ the set of variables occurring in it. The following equalities hold.*

$$\begin{aligned} \text{vars}(\alpha) &= \{\alpha\} & \text{vars}(T_1 \rightarrow T_2) &= \text{vars}(T_1) \cup \text{vars}(T_2) & \text{vars}(b) &= \emptyset \\ \text{vars}(\theta) &= \{\theta\} & \text{vars}(T_1 \vee T_2) &= \text{vars}(T_1) \cup \text{vars}(T_2) & \text{vars}(\perp) &= \emptyset \\ \text{vars}(\langle \ell = \tau_\ell \rangle_{\ell \in L_1} \mid \zeta \rangle^{L_2}) &= \{\zeta\} \cap \mathcal{V}_r & \text{vars}(\neg T) &= \text{vars}(T) & \text{vars}(\emptyset) &= \emptyset \\ \text{vars}(R) &= \text{vars}(\text{row}(R)) \end{aligned}$$

LEMMA B.1. *If $t_1 \leq t_2$ with $t_2 \leq \{\mid..\}$ then $t_1 \setminus \ell \leq t_2 \setminus \ell$.*

PROOF. We show that for any $t \leq \{\mid..\}$, we have $\llbracket t \setminus \ell \rrbracket^{\text{row}} = \bigcup_{(\text{Rec}(\vec{a})^{V:t})} \vec{d} \setminus \ell$, where $\langle \ell = \tau_\ell \rangle_{\ell \in L, -} = \perp^0 \rangle_{\emptyset}^V \setminus \ell = \{\langle \ell = \tau_\ell \rangle_{\ell \in L \setminus \{-\}} = \perp^0 \rangle_{\{\ell\}}^{(V \setminus V_\ell) \cup V'} \mid V' \subseteq V_\ell\}$, where for all $\ell \in L$, $V_\ell \stackrel{\text{def}}{=} \{\rho \mid \ell \in \text{dom}(\rho)\}$.

We start with $\bigcup_{(\text{Rec}(\vec{a})^{V:t})} \vec{d} \setminus \ell \subseteq \llbracket t \setminus \ell \rrbracket^{\text{row}}$. Let $(\text{Rec}(\langle \ell = \delta_\ell \rangle_{\ell \in L \cup \{\ell\}, -} = \perp^0 \rangle_{\emptyset}^V)^{V_0} : t)$ and t in DNF. Let $\vec{d}_\ell = \langle \ell = \tau_\ell \rangle_{\ell \in L, -} = \perp^0 \rangle_{\{\ell\}}^{(V \setminus V_\ell) \cup V'}$ with $V' \subseteq V_\ell$. The proof is by induction on the top-level type connectives of t .

- $t = \langle \ell = \tau_\ell \rangle_{\ell \in L'} \mid \rho \rangle$.
 - $\ell \in L'$ or $\zeta \notin \mathcal{V}_r$. Then $t \setminus \ell = \langle \ell = \tau_\ell \rangle_{\ell \in L' \setminus \{\ell\}} \mid \zeta \rangle^{\{\ell\}}$ and it is clear that $(\vec{d}_\ell : t \setminus \ell)$.
 - $\ell \notin L'$ and $\zeta = \rho \in \mathcal{V}_r$. Then $t \setminus \ell = \langle \ell = \tau_\ell \rangle_{\ell \in L'} \mid .. \rangle^{\{\ell\}}$. By construction, for each $\ell \in L'$, we have either $(\delta_\ell : t(\ell))$ if $\ell \in L$, or $(\perp^0 : t(\ell))$ otherwise. So $(\vec{d}_\ell : t \setminus \ell)$ since there is no constraint on the tagged set of variables in the interpretation of $t \setminus \ell$.
- $t = \neg \langle \ell = \tau_\ell \rangle_{\ell \in L'} \mid \zeta \rangle$.
 - $\ell \in L'$ or $\zeta \notin \mathcal{V}_r$. Without loss of generality, we can suppose $\ell \in L'$ even in the second case. If $\tau_\ell \neq \perp \vee \perp$, then $t \setminus \ell = \langle \mid..\rangle^{\{\ell\}}$ and $(\vec{d}_\ell : t \setminus \ell)$ is trivial. If $\tau_\ell = \perp \vee \perp$, then $t \setminus \ell = \neg \langle \ell = \tau_\ell \rangle_{\ell \in L' \setminus \{\ell\}} \mid \zeta \rangle^{\{\ell\}}$ and there is $\ell' \neq \ell$ such that $(\delta_{\ell'} : t(\ell'))$ is false, or $(\perp^0 : t(\ell'))$ is false. Thus, $(\vec{d}_\ell : t \setminus \ell)$.
 - $\ell \notin L'$ and $\zeta = \rho \in \mathcal{V}_r$. Then $t \setminus \ell = \langle \mid..\rangle^{\{\ell\}}$ and $(\vec{d}_\ell : t \setminus \ell)$ is trivial.

- $t = t_1 \wedge t_2$. We have $t \setminus \ell = t_1 \setminus \ell \wedge t_2 \setminus \ell$. By induction hypothesis, $(\vec{d} \setminus \ell : t_i \setminus \ell)$ for $i \in \{1, 2\}$, so $(\vec{d} \setminus \ell : t \setminus \ell)$.
- $t = t_1 \vee t_2$. We have $t \setminus \ell = t_1 \setminus \ell \vee t_2 \setminus \ell$. By induction hypothesis, there is $i \in \{1, 2\}$ such that $(\vec{d} \setminus \ell : t_i \setminus \ell)$. Thus, $(\vec{d} \setminus \ell : t \setminus \ell)$.

Now, we consider $\llbracket t \setminus \ell \rrbracket^{\text{row}} \subseteq \bigcup_{(\text{Rec}(\vec{d}))^V : t} \vec{d} \setminus \ell$. If $t \leq \emptyset$, then by definition $t \setminus \ell \leq \emptyset$. Otherwise, let $(\vec{d}_\ell : t \setminus \ell)$ and $t = \bigvee_{i \in I} \bigwedge_{R \in P_i} R \wedge \bigwedge_{R \in N_i} \neg R$. For each $i \in I$, let $P_{\mathcal{V}}^i = \{R \in P_i \mid \text{tail}(R) = \rho \text{ and } \ell \notin \text{def}(\rho)\}$, similarly for $N_{\mathcal{V}}^i$. By the reasoning of [Lemma C.4](#), we have

$$\begin{aligned} t &\simeq \bigvee_{i \in I} \bigvee_{N'_i \subseteq N_i} \bigvee_{N'_{i,\mathcal{V}} \subseteq N'_i \cap N_{\mathcal{V}}^i} t_{N'_{i,\mathcal{V}}} \\ &= \bigvee_{i \in I} \bigvee_{N'_i \subseteq N_i} \bigvee_{N'_{i,\mathcal{V}} \subseteq N'_i \cap N_{\mathcal{V}}^i} \left(\{\ell = \bigwedge_{R \in P_i} R(\ell) \wedge \bigwedge_{R \in N_i \setminus N'_i} \neg R(\ell) \mid \dots\} \wedge \bigwedge_{R \in P_i} \{\ell \mid \text{row}(R) \setminus \ell\} \right. \\ &\quad \left. \wedge \bigwedge_{R \in N'_i \setminus N'_{i,\mathcal{V}}} \neg \{\ell \mid \text{row}(R) \setminus \ell\} \wedge \bigwedge_{R \in P_{\mathcal{V}}^i} \{\text{lab}(R) \mid \text{tail}(R)\} \wedge \bigwedge_{R \in N'_{i,\mathcal{V}}} \neg \{\text{lab}(R) \mid \text{tail}(R)\} \right) \end{aligned}$$

where $\text{row}(R) \setminus \ell$ is the operation defined on positive atomic row types in [Definition C.6](#). This operation coincides with $R \setminus \ell$ on a positive and atomic R . For each i and $N'_{i,\mathcal{V}}$, we have $t_{N'_{i,\mathcal{V}}} \setminus \ell = \bigwedge_{R \in P_i} \{\ell \mid \text{row}(R) \setminus \ell\} \wedge \bigwedge_{R \in N'_i \setminus N'_{i,\mathcal{V}}} \neg \{\ell \mid \text{row}(R) \setminus \ell\}$. By hypothesis, there are $i \in I$ and $N'_{i,\mathcal{V}}$ such that $(\vec{d}_\ell : t_{N'_{i,\mathcal{V}}} \setminus \ell)$. Let δ_ℓ be such that $(\delta_\ell : \bigwedge_{R \in P_i} R(\ell) \wedge \bigwedge_{R \in N'_i} \neg R(\ell))$. Let $V = (\text{tag}(\vec{d}_\ell) \cup \{\text{tail}(R) \mid R \in P_{\mathcal{V}}^i\}) \setminus \{\text{tail}(R) \mid R \in N'_{i,\mathcal{V}}\}$. We take \vec{d} to be \vec{d}_ℓ completed by $\ell = \delta$ and with $\text{tag}(\vec{d}) = V$ and we have $(\text{Rec}(\vec{d}))^V : t$. Since $\{\text{tail}(R) \mid R \in P_{\mathcal{V}}^i\}$ and $\{\text{tail}(R) \mid R \in N'_{i,\mathcal{V}}\}$ are subsets of V_ℓ , we have $\vec{d}_\ell \in \vec{d} \setminus \ell$.

For the second case to work, we need to show that for all $t \leq \{\mid \dots\}$, $t \setminus \ell \simeq \text{split}(t) \setminus \ell$, where $\text{split}(t)$ is the type obtained by the previous decomposition. First, let $t = \bigwedge_{R \in P} R \wedge \bigwedge_{R \in N} \neg R$. The proof is by induction on $|N|$. Let $P_{\mathcal{V}}$ and $N_{\mathcal{V}}$ be defined as before relative to P and N .

- $N = \emptyset$. Then,

$$\text{split}(t) = \{\ell = \bigwedge_{R \in P} R(\ell) \mid \dots\} \wedge \bigwedge_{R \in P} \{\ell \mid \text{row}(R) \setminus \ell\} \wedge \bigwedge_{R \in P_{\mathcal{V}}} \{\text{lab}(R) \mid \text{tail}(R)\}$$

and $\text{split}(t) \setminus \ell = \bigwedge_{R \in P} \text{row}(R) \setminus \ell = t \setminus \ell$.

- $N = N_0 \cup \{R_n = \{\ell = \tau \mid r\}\}$ where r is an atomic row. By equivalence, this covers all cases where $\text{tail}(R_n) \notin \mathcal{V}_r$ and the ones where $\text{tail}(R_n) = \rho$ and $\ell \notin \text{def}(\rho)$. Let $t_0 = \bigwedge_{R \in P} R \wedge \bigwedge_{R \in N_0} \neg R$, so that $t \setminus \ell = t_0 \setminus \ell \wedge R_n \setminus \ell$. The type t is decomposed as follows:

$$\begin{aligned} \text{split}(t) &= \bigvee_{N' \subseteq N_0} \bigvee_{N'_{\mathcal{V}} \subseteq N' \cap N_{\mathcal{V}}} \bigvee_{k \in \{0,1\}} \left(\{\ell = \bigwedge_{R \in P} R(\ell) \wedge \bigwedge_{R \in N \setminus N'} R(\ell) \bigwedge_{k=0} \neg \tau \mid \dots\} \right. \\ &\quad \left. \wedge \bigwedge_{R \in P} \{\ell \mid \text{row}(R) \setminus \ell\} \wedge \bigwedge_{R \in N' \setminus N'_{\mathcal{V}}} \neg \{\ell \mid \text{row}(R) \setminus \ell\} \bigwedge_{k=1} \neg \{\ell \mid r\} \right. \\ &\quad \left. \wedge \bigwedge_{R \in P_{\mathcal{V}}} \{\text{lab}(R) \mid \text{tail}(R)\} \wedge \bigwedge_{R \in N'_{\mathcal{V}}} \neg \{\text{lab}(R) \mid \text{tail}(R)\} \right) \end{aligned}$$

There are two cases.

- (1) $\tau = \mathbb{1} \vee \perp$. Since $\neg\tau = \mathbb{0}$, the disjunction with $k = 0$ is empty, and the DNF of $\text{split}(t)$ is equal to

$$\bigvee_{N' \subseteq N_0} \bigvee_{N'_V \subseteq N' \cap N_V} \left(\{\ell = \bigwedge_{R \in P} R(\ell) \wedge \bigwedge_{R \in N \setminus N'} R(\ell) | \dots\} \right. \\ \left. \wedge \bigwedge_{R \in P} \{\ell | \text{row}(R) \setminus \ell\} \wedge \bigwedge_{R \in N' \setminus N'_V} \neg\{\ell | \text{row}(R) \setminus \ell\} \right) \wedge \neg\{\ell | r\}$$

which is equal to $\text{split}(t_0) \wedge \neg\{\ell | r\}$. So by induction hypothesis and since $R_n \setminus \ell = \neg r$,

$$\text{split}(t) \setminus \ell = \text{split}(t_0) \setminus \ell \wedge \neg r \simeq t_0 \setminus \ell \wedge \neg r = t \setminus \ell$$

- (2) $\tau \neq \mathbb{1} \vee \perp$. Then, $\text{split}(t) \setminus \ell$ is equal to

$$\bigvee_{N' \subseteq N_0} \bigvee_{N'_V \subseteq N' \cap N_V} \left(\bigwedge_{R \in P} \text{row}(R) \setminus \ell \wedge \bigwedge_{R \in N' \setminus N'_V} \neg(\text{row}(R) \setminus \ell) \right. \\ \left. \vee \bigwedge_{R \in P} \text{row}(R) \setminus \ell \wedge \bigwedge_{R \in N' \setminus N'_V} \neg(\text{row}(R) \setminus \ell) \wedge \bigwedge_{R \in N' \setminus N'_V} \neg r \right)$$

So that $\text{split}(t) \setminus \ell$ is trivially equivalent to $\text{split}(t_0) \setminus \ell$, and by induction hypothesis and the fact that $R_n \setminus \ell = \langle | \dots \rangle^\ell$ we have $\text{split}(t_0) \setminus \ell \simeq t_0 \setminus \ell = t \setminus \ell$.

- $N = N_0 \cup \{R_n = \{(\ell' = \tau_{\ell'}^{\ell'} | \rho)\}\}$ where $\ell \notin L$. Let $t_0 = \bigwedge_{R \in P} R \wedge \bigwedge_{R \in N_0} \neg R$, so that $t \setminus \ell = t_0 \setminus \ell \wedge R_n \setminus \ell$. The type t is decomposed as follows:

$$\text{split}(t) = \bigvee_{N' \subseteq N_0} \bigvee_{N'_V \subseteq N' \cap N_V} \bigvee_{k \in \{1,2\}} \left(\{\ell = \bigwedge_{R \in P} R(\ell) \wedge \bigwedge_{R \in N \setminus N'} R(\ell) | \dots\} \right. \\ \wedge \bigwedge_{R \in P} \{\ell | \text{row}(R) \setminus \ell\} \wedge \bigwedge_{R \in N' \setminus N'_V} \neg\{\ell | \text{row}(R) \setminus \ell\} \bigwedge_{k=1} \neg\{\ell = \mathbb{1} \vee \perp, (\ell' = \tau_{\ell'}^{\ell'} | \dots)\} \\ \left. \wedge \bigwedge_{R \in P_V} \{\text{lab}(R) | \text{tail}(R)\} \wedge \bigwedge_{R \in N'_V} \neg\{\text{lab}(R) | \text{tail}(R)\} \bigwedge_{k=2} \neg\{L | \rho\} \right)$$

Thus, $\text{split}(t) \setminus \ell$ is trivially equivalent to the type in case (2) above (with $\neg\{(\ell' = \tau_{\ell'}^{\ell'} | \dots)\}^{\ell'}$ instead of $\neg r$ in the second line), which is equal to $\text{split}(t_0) \setminus \ell$ and we conclude in the same way since here also $R_n \setminus \ell = \langle | \dots \rangle^{\ell'}$.

Now, if $t = \bigvee_{i \in I} t_i$ where the t_i 's are conjunctions, we have $t \setminus \ell = \bigvee_{i \in I} (t_i \setminus \ell) \simeq \bigvee_{i \in I} (\text{split}(t_i) \setminus \ell) = \text{split}(t) \setminus \ell$. \square

LEMMA B.2 (INVERSION). *Let $v = \{v_1 \text{ with } \ell = v_2\}$. If there is a derivation $\Delta \mid \Gamma \vdash_{\mathcal{D}} v : t$, then there are derivations $\Delta \mid \Gamma \vdash_{\mathcal{D}} v_1 : t_1 \leq \{\ell = \perp | \dots\}$ and $\Delta \mid \Gamma \vdash_{\mathcal{D}} v_2 : t_2$ such that $\{\ell = t_2 | t_1 \setminus \ell\} \leq t$.*

PROOF. By induction on $\Delta \mid \Gamma \vdash_{\mathcal{D}} v : t$, with a case analysis on the last rule used, that has to be of (EXT), (INTER) or (SUB).

(EXT) Straightforward.

(INTER) We apply the induction hypothesis twice. Since both types obtained are supertypes of $\{\ell = t_2 | t_1 \setminus \ell\}$, their intersection is also.

(SUB) By induction hypothesis and transitivity of subtyping. \square

LEMMA B.3 (SUBJECT REDUCTION). *Let e be an expression and t a type. If $\Delta \mid \Gamma \vdash_{\mathcal{D}} e : t$ and $e \rightsquigarrow e'$, then $\Delta \mid \Gamma \vdash_{\mathcal{D}} e' : t$.*

PROOF. The proof is by induction on the derivation of $\Delta \mid \Gamma \vdash_{\mathcal{D}} e : t$ and by a case analysis on the last rule used in the derivation of $\Delta \mid \Gamma \vdash_{\mathcal{D}} e : t$. We detail the cases related to the rules for records, for the rest, see e.g. [22].

(EMP) $e = \{\}$, so it does not reduce.

(EXT) $e = \{e_1 \text{ with } \ell = e_2\}$. Necessarily, we have $e' = \{e'_1 \text{ with } \ell = e_2\}$ or $e' = \{e_1 \text{ with } \ell = e'_2\}$ and this is direct by induction hypothesis.

(SEL) If $e = e_0.\ell \rightsquigarrow e'_0.\ell = e'$ or if $e = \{e_1 \text{ with } \ell' = e_2\}.\ell$ and the reduction occurs in e_1 or e_2 , this is direct by induction hypothesis. Otherwise, we have $e = \{v \text{ with } \ell' = v'\}.\ell$ and $\Delta \mid \Gamma \vdash_{\mathcal{D}} \{v \text{ with } \ell' = v'\} : \{\ell = t \mid \dots\}$. By **Lemma B.2**, there are derivations $\Delta \mid \Gamma \vdash_{\mathcal{D}} v : t_1 \leq \{\ell' = \perp \mid \dots\}$ and $\Delta \mid \Gamma \vdash_{\mathcal{D}} v' : t_2$ such that $\{\ell' = t_2 \mid t_1 \setminus \ell'\} \leq \{\ell = t \mid \dots\}$.

- If $\ell = \ell'$, then $e' = v'$. Since $\{\ell = t_2 \mid t_1 \setminus \ell\} \leq \{\ell = t \mid \dots\}$, we have $t_2 \leq t$ and we conclude by (SUB).

- If $\ell \neq \ell'$, then $e' = v.\ell$. Since $\{\ell' = t_2 \mid t_1 \setminus \ell'\} \leq \{\ell = t \mid \dots\}$, we have $t_1 \leq \{\ell = t, \ell' = \perp \mid \dots\}$. We conclude by rules (SUB) and (SEL).

(DEL) If $e = \{\}\ell \rightsquigarrow \{\}$, since $\{\}\ell = \{\}$, we can use the same derivation. If $e = \{e_1 \text{ with } \ell' = e_2\}\ell$ and the reduction occurs in e_1 or e_2 , this is direct by induction hypothesis. Otherwise, we have $e = \{v \text{ with } \ell' = v'\}\ell$. By **Lemma B.2**, there are derivations $\Delta \mid \Gamma \vdash_{\mathcal{D}} v : t_1 \leq \{\ell' = \perp \mid \dots\}$ and $\Delta \mid \Gamma \vdash_{\mathcal{D}} v' : t_2$ such that $\{t_1 \text{ with } \ell' = t_2\} \leq t$.

- If $\ell = \ell'$, then $e' = v\ell$. Since $t_1 \leq \{\ell = \perp \mid \dots\}$, v can be typed with $t_1 = t_1 \setminus \ell = \{t_1 \text{ with } \ell = t_2\} \setminus \ell$. We conclude because $\{t_1 \text{ with } \ell = t_2\} \leq t$.

- If $\ell \neq \ell'$, then $e' = \{v\ell \text{ with } \ell' = v'\}$. There is a derivation $\Delta \mid \Gamma \vdash_{\mathcal{D}} v\ell : t_1 \setminus \ell$. Since $\{t_1 \setminus \ell \text{ with } \ell' = t_2\} = \{t_1 \text{ with } \ell' = t_2\} \setminus \ell$, we conclude by rule (EXT).

(INST) Direct by induction hypothesis. □

LEMMA B.4 (GENERATION FOR VALUES). *Let v be a value such that $\Delta \mid \Gamma \vdash_{\mathcal{D}} v : t$ with $t \leq \{\mid \dots\}$. Then v has one of the forms $\{\}$ or $\{v_1 \text{ with } \ell = v_2\}$.*

PROOF. It is easy to see that a derivation for v is obtained by a rule (EMP) followed by rules (EXT), (INTER) or (SUB). Remark that there are no rules (INST) because it is impossible to derive a polymorphic type t for v , in particular since for instance $\{\mid \epsilon\} \not\leq \{\mid \rho\}$. Moreover, we can show by induction on the depth of the derivation that if $\Delta \mid \Gamma \vdash_{\mathcal{D}} v : t$ is derivable, then $t \neq \emptyset$. The proof is by induction on the derivation.

(EMP) This is the base case, where $v = \{\}$.

(EXT) v is of the second form.

(INTER) t_1 and t_2 are reducible to disjunctive normal forms $t_1^R \wedge t'_1$ and $t_2^R \wedge t'_2$, such that $t_1^R, t_2^R \leq \{\mid \dots\}$ and by hypothesis, $t'_1 \wedge t'_2 \leq \emptyset$. We can show by induction on the derivation of v that this last property does not hold if v is not a record expression.

(SUB) We have $\Delta \mid \Gamma \vdash_{\mathcal{D}} v : t' \leq t$. $t' \not\leq \emptyset$ since v is a value, so we can apply the induction hypothesis. □

LEMMA B.5 (PROGRESS). *Let e be a well-typed closed expression, that is, $\emptyset \mid \emptyset \vdash_{\mathcal{D}} e : t$ for some t . If e is not a value, then there exists an expression e' such that $e \rightsquigarrow e'$.*

PROOF. The proof is by induction on the derivation of $\Delta \mid \Gamma \vdash_{\mathcal{D}} e : t$ and by a case analysis on the last rule used in the derivation of $\Delta \mid \Gamma \vdash_{\mathcal{D}} e : t$. We detail the cases related to records, for the rest, see e.g. [22].

(EMP) $e = \{\}$ is a value.

(EXT) $e = \{e_1 \text{ with } \ell = e_2\}$. If e_1 or e_2 can be reduced, e can also. Otherwise, e_1 and e_2 are values by induction and so is e .

- (DEL)** $e = e_0 \setminus \ell$. If e_0 can be reduced, so can e . Otherwise, we have by induction hypothesis that e_0 is a value. By [Lemma B.4](#), either $e_0 = \{v \text{ with } \ell' = v'\}$ and e reduces with $[R_{\text{del}}^-]$ or $[R_{\text{del}}^\neq]$, or $e_0 = \{\}$ and e reduces with $[R_{\text{emp}}]$.
- (SEL)** $e = e_0 \cdot \ell$. If e_0 can be reduced, so can e . Otherwise, we have by induction hypothesis that e_0 is a value. By [Lemma B.4](#), $e_0 = \{v \text{ with } \ell' = v'\}$ or $e_0 = \{\}$. In the first case, e reduces with $[R_{\text{del}}^-]$ or $[R_{\text{del}}^\neq]$. The second case is impossible, since there is no derivation for e_0 of type $\{\ell = t \mid \dots\}$.
- (INST)** Directly by induction hypothesis. \square

THEOREM 3.1 (TYPE SOUNDNESS). *Let e be a well-typed closed expression, that is, $\emptyset \mid \emptyset \vdash_{\mathcal{D}} e : t$ for some t . Then either e diverges or it reduces to a value of type t .*

PROOF. Consequence of [Lemmas B.3](#) and [B.5](#). \square

B.2 Algorithmic Type System

B.2.1 Field selection. We remind here the definition of the field selection operator.

DEFINITION 3.1 (FIELD SELECTION). *Let $t \leq \{\ell = \mathbb{1} \mid \dots\}$ be a DNF. We define the selection of the field ℓ of t as $(\bigvee_{i \in I} t_i) \cdot \ell \stackrel{\text{def}}{=} \bigvee_{i \in I} t_i \cdot \ell$ and*

$$\left(\bigwedge_{R \in P} R \wedge \bigwedge_{R \in N} \neg R \wedge \bigwedge_{\alpha \in V_p} \alpha \wedge \bigwedge_{\alpha \in V_n} \neg \alpha \right) \cdot \ell \stackrel{\text{def}}{=} \bigvee_{N' \subseteq N} \left(\bigwedge_{R \in P} R(\ell) \wedge \bigwedge_{R \in N'} \neg R(\ell) \right)$$

For an arbitrary type $t \leq \{\ell = \mathbb{1} \mid \dots\}$, we define $t \cdot \ell \stackrel{\text{def}}{=} (\text{dnf}(t \wedge \{\ell = \mathbb{1} \mid \dots\}))$.

LEMMA B.6. *Let $t = \bigwedge_{R \in P} R \wedge \bigwedge_{R \in N} \neg R$ and $\rho \in \mathcal{V}_r$ such that $\rho \notin \text{tlv}(\text{row}(t))$. Then, $t \wedge \{\mathcal{L} \setminus \text{def}(\rho) \mid \rho\} \leq \emptyset \iff t \leq \emptyset$.*

PROOF. Because $\rho \notin \text{tlv}(\text{row}(t))$, the set of elements $\text{Rec}(\vec{d}) \in \llbracket t \cdot \ell \rrbracket$ is exactly the elements of $\llbracket t \rrbracket$, where ρ is added from $\text{tag}(\vec{d})$. \square

LEMMA B.7. *Let $t \leq \{\ell = \mathbb{1} \mid \dots\}$. Then, for all t_ℓ , $t \leq \{\ell = t_\ell \mid \dots\} \iff t \cdot \ell \leq t_\ell$. In particular, $t \cdot \ell \leq \mathbb{1}$ and $t \leq \{\ell = t \cdot \ell \mid \dots\}$.*

PROOF. By [Lemma C.4](#), t is equivalent to:

$$\begin{aligned} & \bigvee_{i \in I} \bigvee_{N' \subseteq N_i} \bigvee_{N'_v \subseteq N' \cap N_{\mathcal{V}}} \left(\{\ell = \bigwedge_{R \in P} R(\ell) \wedge \bigwedge_{R \in N \setminus N'} \neg R(\ell) \mid \dots\} \right. \\ & \quad \wedge \bigwedge_{R \in P} \{\ell = \mathbb{1} \vee \perp \mid R \setminus \ell\} \wedge \bigwedge_{R \in N' \setminus N'_v} \neg \{\ell = \mathbb{1} \vee \perp \mid R \setminus \ell\} \\ & \quad \left. \wedge \bigwedge_{R \in P_{\mathcal{V}}} \{\text{lab}(R) \mid \text{tail}(R)\} \wedge \bigwedge_{R \in N'_v} \neg \{\text{lab}(R) \mid \text{tail}(R)\} \right) \end{aligned}$$

where $P_{\mathcal{V}} = \{R \in P \mid \text{tail}(R) = \rho \text{ and } \ell \in \text{def}(\rho)\}$, similarly for $N_{\mathcal{V}}$, and because for any atom R , $\text{row}(R) \setminus \{\ell\} = R \setminus \ell$. Then, for any t_ℓ it is clear that $t \leq \{\ell = t_\ell \mid \dots\}$ is equivalent to $t \cdot \ell \leq t_\ell$. \square

COROLLARY B.8. *Let $t \leq \{\ell = \mathbb{1} \mid \dots\}$ and $[\sigma_i]_{i \in I}$ be a set of substitutions. Then $(\bigwedge_{i \in I} t \sigma_i) \cdot \ell \leq \bigwedge_{i \in I} t \cdot \ell \sigma_i$.*

B.2.2 Taming non-structural rules. To prove soundness and completeness of the algorithmic type system, we go through an intermediate type system, where the intersection rule is n-ary, and the introduction of a term variable can perform a renaming of polymorphic variables. The introduction of a renaming aims at eliminating trivial instantiations (only renamings) in the uses of (INST). More details are given by [9, Section I.1].

$$\text{(VAR)} \frac{}{\Delta \mid \Gamma \vdash_m x : \Gamma(x)\sigma} \quad \begin{array}{l} x \in \text{dom}(\Gamma) \\ \text{dom}(\sigma) \cap \Delta = \emptyset \\ \text{and } \sigma \text{ is a renaming} \end{array} \quad \text{(INTER)} \frac{(\Delta \mid \Gamma \vdash_m e : t_i)_{i \in I} \quad |I| > 0}{\Delta \mid \Gamma \vdash_m e : \bigwedge_{i \in I} t_i}$$

Rules different from (INST) and (VAR) are the same as in the declarative type system.

LEMMA B.9. $\Delta \mid \Gamma \vdash_m e : t \iff \Delta \mid \Gamma \vdash_D e : t$.

PROOF. The left-to-right direction is straightforward since the rules in the intermediate system generalize the ones of the declarative system. The right-to-left direction is obtained by replacing instances of (VAR) by instances of (VAR) followed by (INST) in the declarative system, and by replacing occurrences of n-ary intersections by $n - 1$ (INTER) nodes. \square

Next, we want to restrict derivations in the intermediate system to a canonical form, where the apparition of (INST) and (SUB) nodes is controlled. For convenience, we introduce the following rule macro:¹⁵

$$\text{(\sqsubseteq)} \frac{\Delta \mid \Gamma \vdash_m e : s}{\Delta \mid \Gamma \vdash_m e : t} \quad s \sqsubseteq_{\Delta} t$$

which stands for (SUB) when $s \leq t$ and otherwise for:

$$\begin{array}{c} \text{(INST)} \frac{\Delta \mid \Gamma \vdash_m e : s}{\Delta \mid \Gamma \vdash_m e : s\sigma_i} \quad \forall i \in I \\ \text{(INTER)} \frac{}{\Delta \mid \Gamma \vdash_m e : \bigwedge_{i \in I} s\sigma_i} \\ \text{(SUB)} \frac{}{\Delta \mid \Gamma \vdash_m e : t} \end{array}$$

DEFINITION B.3 (CANONICAL DERIVATION). *A derivation is canonical if every (INST) node it contains is part of a (\sqsubseteq) pattern and every (\sqsubseteq) and (SUB) nodes are either:*

- The premise of an (DEL) or (SEL) node, or
- The first premise of a (EXT) node, or
- One of the premises of an (ABS) or (APP) node.

LEMMA B.10. *A derivation of $\Delta \mid \Gamma \vdash_m e : t$ can be transformed into a derivation $\Delta \mid \Gamma \vdash_m e : t\sigma$, for any renaming σ such that $\text{dom}(\sigma) \cap \Delta = \emptyset$, without changing the structure of the derivation.*

PROOF. As in [9, Lemma I.14]. \square

LEMMA B.11. *Let I, Δ and $t'_i \sqsubseteq_{\Delta} t_i$ for all $i \in I$. Then, $\bigwedge_{i \in I} t'_i \sqsubseteq_{\Delta} \bigwedge_{i \in I} t_i$.*

PROOF. As in [9, Proposition I.15]. \square

LEMMA B.12. *Let $s' \sqsubseteq_{\Delta} s, \ell$ and r of definition space $\mathcal{L} \setminus \ell$ such that $\text{vars}(s') \cap \text{vars}(r) \subseteq \Delta$. Then, $\{\ell = s' \mid r\} \sqsubseteq_{\Delta} \{\ell = s \mid r\}$.*

PROOF. Let $\{\sigma_i\}_{i \in I}$ such that $\bigwedge_{i \in I} s'\sigma_i \leq s$, with $\text{dom}(\sigma) \subseteq \text{vars}(s')$. We have $\bigwedge_{i \in I} \{\ell = s' \mid r\}\sigma_i \simeq \{\ell = \bigwedge_{i \in I} s'\sigma_i \mid r\} \leq \{\ell = s \mid r\}$. \square

¹⁵In the appendix, we also use the metavariable s for types.

LEMMA B.13. *Any derivation of $\Delta \mid \Gamma \vdash_m e : t$ can be transformed into a canonical derivation of $\Delta \mid \Gamma \vdash_m e : t'$, where $t' \sqsubseteq_{\Delta} t$.*

PROOF. By induction on the size of the derivation and through a case analysis on the root of the derivation tree used.

(INST) or (SUB) We remove the root and let its premise be the new one.

(INTER) Let $t = \bigwedge_{i \in I} s_i$. By induction hypothesis, for all $i \in I$ we have derivations $\Delta \mid \Gamma \vdash_m e : s'_i$ with $s'_i \sqsubseteq_{\Delta} s_i$. By rule (INTER), we have a derivation of $t' = \bigwedge_{i \in I} s'_i$, and $t' \sqsubseteq_{\Delta} t$ is verified by Lemma B.11.

(CONST), (VAR), (EMP) Already canonical.

(EXT) Let $e = \{e_1 \text{ with } \ell = e_2\}$ and $t = \{\ell = t_2 \mid t_1 \setminus \ell\}$. By induction hypothesis, we have canonical derivations $\Delta \mid \Gamma \vdash_m e_1 : t'_1$ and $\Delta \mid \Gamma \vdash_m e_2 : t'_2$ with $t'_1 \sqsubseteq_{\Delta} t_1$ and $t'_2 \sqsubseteq_{\Delta} t_2$. By rule (\sqsubseteq), we derive $\Delta \mid \Gamma \vdash_m e_1 : t_1$. Let $t' = \{\ell = t'_2 \mid t_1\}$. Rule (EXT) node gives a canonical derivation of $\Delta \mid \Gamma \vdash_m e : t'$. We can suppose that the variables in t'_2 and t_1 are disjoint (otherwise we use Lemma B.10), and conclude $t' \sqsubseteq_{\Delta} t$ by Lemma B.12.

(ABS) By induction hypothesis, for each $i \in I$ we have derivations $\Delta \cup \text{vars}(t) \mid \Gamma, x : t_i \vdash_m e : s'_i$ with $s'_i \sqsubseteq_{\Delta} s_i$. By rule (\sqsubseteq), we have derivations $\Delta \cup \text{vars}(t) \mid \Gamma, x : t_i \vdash_m e : s_i$ and we conclude by rule (ABS).

(APP), (SEL), (DEL) Similar to the previous case. □

B.2.3 Soundness and completeness.

THEOREM 3.2 (SOUNDNESS). *If $\Delta \mid \Gamma \vdash_{\mathcal{A}} e : t$, then $\Delta \mid \Gamma \vdash_{\mathcal{D}} e : t$.*

PROOF. By induction on the algorithmic typing derivation. By Lemma B.9, it suffices to give a derivation $\Delta \mid \Gamma \vdash_m e : t$. We proceed by a case analysis on the last rule used in the derivation.

(CONST), (VAR) Straightforward.

(ABS) By induction hypothesis, for each $i \in I$ we have $\Delta \cup \Delta' \mid \Gamma, x : t_i \vdash_m e : s'_i$. Since $s'_i \sqsubseteq_{\Delta \cup \Delta'} s_i$, we derive $\Delta \cup \Delta' \mid \Gamma, x : t_i \vdash_m e : s_i$ by rule (\sqsubseteq). We conclude by rule (ABS) in the declarative system.

(APP) By hypothesis, we have $t \in t_1 \bullet_{\Delta} t_2$, so t is such that there are two substitution sets with $\bigwedge_{j \in J} t_1 \sigma_j \leq \bigwedge_{i \in I} t_2 \sigma_i \rightarrow t$. By induction hypothesis and (\sqsubseteq), we obtain $\Delta \mid \Gamma \vdash_m e_1 : \bigwedge_{j \in J} t_1 \sigma_j$ and $\Delta \mid \Gamma \vdash_m e_2 : \bigwedge_{i \in I} t_2 \sigma_i$. By (SUB), we have $\Delta \mid \Gamma \vdash_m e_1 : \bigwedge_{i \in I} t_2 \sigma_i \rightarrow t$. We conclude by rule (APP) in the declarative system.

(EMP) Straightforward.

(EXT) By induction hypothesis, we have $\Delta \mid \Gamma \vdash_m e : t$, $\Delta \mid \Gamma \vdash_m e' : t'$ and sets of substitutions $[\sigma_i]_{i \in I}$ such that $\bigwedge_{i \in I} t \sigma_i \leq \{\mid \dots\}$ and $r = (\bigwedge_{i \in I} t \sigma_i) \setminus \ell$. By rules (INST) and (INTER), we have $\Delta \mid \Gamma \vdash_m e : \bigwedge_{i \in I} t \sigma_i$, and we conclude with rule (DEL).

(DEL) Similar to the case for (EXT), without the derivation of t' .

(SEL) By induction hypothesis, we have $\Delta \mid \Gamma \vdash_m e : t$ and a set of substitutions $[\sigma_i]_{i \in I}$ such that $\bigwedge_{i \in I} t \sigma_i \leq \{\ell = \mathbb{1} \mid \dots\}$ and $t_{\ell} = (\bigwedge_{i \in I} t \sigma_i) \cdot \ell$. By Lemma B.7, we have $\bigwedge_{i \in I} t \sigma_i \leq \{\ell = t_{\ell} \mid \dots\}$, so we conclude with rule (\sqsubseteq) and (SEL). □

THEOREM 3.3 (COMPLETENESS). *If $\Delta \mid \Gamma \vdash_{\mathcal{D}} e : t$, then there is t' such that $\Delta \mid \Gamma \vdash_{\mathcal{A}} e : t'$ and $t' \sqsubseteq_{\Delta} t$.*

PROOF. By Lemmas B.9 and B.13 we transform the input derivation into a canonical derivation $\Delta \mid \Gamma \vdash_m e : s$, where $s \sqsubseteq_{\Delta} t$. The proof is by induction on that derivation (where we use (\sqsubseteq) instead of the corresponding pattern). In the end, we obtain $\Delta \mid \Gamma \vdash_{\mathcal{A}} e : t'$ with $t' \sqsubseteq_{\Delta} s$ and thus conclude since by transitivity of \sqsubseteq_{Δ} , we have $t' \sqsubseteq_{\Delta} t$.

(CONST), (VAR) Straightforward.

$$\begin{array}{c}
\text{(EXT)} \frac{\Delta \mid \Gamma \vdash e : t \leq \{\ell = \perp \mid \dots\} \quad \Delta \mid \Gamma \vdash e' : t'}{\Delta \mid \Gamma \vdash \{e \text{ with } \ell = e'\} : \{\ell = t' \mid t \setminus \ell\}} \quad \text{(DEL)} \frac{\Delta \mid \Gamma \vdash e : t \leq \{\dots\}}{\Delta \mid \Gamma \vdash e \setminus \ell : \{\ell = \perp \mid t \setminus \ell\}} \\
\text{(SEL)} \frac{\Delta \mid \Gamma \vdash e : t}{\Delta \mid \Gamma \vdash e.\ell : t.\ell}
\end{array}$$

The rules (CONST), (VAR), (ABS), (APP), (EMP) are the same as in the algorithmic system.

Fig. 4. Alternative algorithmic system

- (ABS)** By induction hypothesis, for each $i \in I$, we have $\Delta \cup \Delta' \mid \Gamma, x : t_i \vdash_{\mathcal{A}} e : s_i$ with $s'_i \sqsubseteq_{\Delta} s_i$. We conclude with rule (ABS) in the algorithmic system.
- (APP)** By induction hypothesis, we have $\Delta \mid \Gamma \vdash_{\mathcal{A}} e_1 : t$ and $\Delta \mid \Gamma \vdash_{\mathcal{A}} e_2 : s$, where $t \sqsubseteq_{\Delta} t_1 \rightarrow t_2$ and $s \sqsubseteq_{\Delta} t_1$. So $t_2 \in t \bullet_{\Delta} s$ since $(t_1 \rightarrow t_2) \cdot t_1 = t_2$.
- (EMP)** Straightforward.
- (EXT)** By induction hypothesis, we have $\Delta \mid \Gamma \vdash_{\mathcal{A}} e : s$, a set of substitutions such that $[\sigma_i]_{i \in I} \Vdash s \sqsubseteq_{\Delta} t \leq \{\ell = \perp \mid \dots\}$, $\Delta \mid \Gamma \vdash_{\mathcal{A}} e' : s'$ and $s' \sqsubseteq_{\Delta} t'$. Thus, we have $[\sigma_i]_{i \in I} \Vdash s \sqsubseteq_{\Delta} \{\ell = \perp \mid \dots\}$. Since $t \leq \{\ell = \perp \mid \dots\}$. Let $r = (\bigwedge_{i \in I} t \sigma_i) \setminus \ell$. By Lemma B.1, we have $r \leq t \setminus \ell$, so that $\{\ell = s' \mid r\} \sqsubseteq_{\Delta} \{\ell = t' \mid \dots\} t \setminus \ell$.
- (DEL)** By induction hypothesis, we have $\Delta \mid \Gamma \vdash_{\mathcal{A}} e : s$ and a set of substitutions such that $[\sigma_i]_{i \in I} \Vdash s \sqsubseteq_{\Delta} t \leq \{\dots\}$. Thus, we have $[\sigma_i]_{i \in I} \Vdash s \sqsubseteq_{\Delta} \{\dots\}$. Let $r = (\bigwedge_{i \in I} t \sigma_i) \setminus \ell$. By Lemma B.1, we have $r \leq t \setminus \ell$, so that $\{\ell = \perp \mid r\} \sqsubseteq_{\Delta} \{\ell = \perp \mid t \setminus \ell\}$.
- (SEL)** By induction hypothesis, we have $\Delta \mid \Gamma \vdash_{\mathcal{A}} e : s$ and a set of substitutions such that $[\sigma_i]_{i \in I} \Vdash s \sqsubseteq_{\Delta} \{\ell = t \mid \dots\}$. Thus, we have $[\sigma_i]_{i \in I} \Vdash s \sqsubseteq_{\Delta} \{\ell = \perp \mid \dots\}$. Let $t_{\ell} = (\bigwedge_{i \in I} s \sigma_i) \setminus \ell$. We have $t_{\ell} \in \Pi_{\Delta}^{\ell}(s)$, and by Lemma B.7 $t_{\ell} \leq t$ so $t_{\ell} \sqsubseteq_{\Delta} t$.
- (\sqsubseteq)** Straightforward by induction hypothesis and transitivity of \sqsubseteq .
- (SUB)** Straightforward by induction hypothesis, inclusion of \leq in \sqsubseteq and transitivity of \sqsubseteq .
- (INTER)** By hypothesis, there is I and derivations $\Delta \mid \Gamma \vdash_m e : s_i$ for all $\{s_i\}_{i \in I}$, with $t = \bigwedge_{i \in I} s_i$. Since the derivation is canonical, we know that each of these derivations ends with (the same kind of) structural rule. According to the other cases, for all $i \in I$ we have derivations $\Delta \mid \Gamma \vdash_m e : s'_i$, where $s'_i \sqsubseteq_{\Delta} s_i$. By Lemma B.11 we have $t' = \bigwedge_{i \in I} s'_i \sqsubseteq_{\Delta} \bigwedge_{i \in I} s_i = t$. \square

B.2.4 Alternative incomplete type system.

LEMMA B.14. *The type system in Fig. 4 is sound with respect to the declarative type system.*

PROOF. Similar to the proof of Theorem 3.2. \square

C APPENDIX FOR TALLYING

We start with giving formal definitions of several notions mentioned in the text.

DEFINITION C.1 (CONSTRAINTS). *A constraint (T_1, c, T_2) is a triple such that $c \in \{\leq, \geq\}$ and $(T_1, T_2) \in (\mathcal{T} \times \mathcal{T}) \cup (\mathcal{T}_{\perp} \times \mathcal{T}_{\perp}) \cup (\mathcal{R} \times \mathcal{R})$. T_1 and T_2 must be of the same kind which, in particular, implies $\text{def}(T_1) = \text{def}(T_2)$ if T_1 and T_2 are rows. We denote with C the set of all constraints.*

Given two sets of constraints $S_1, S_2 \subseteq \mathcal{P}(C)$, we define their union as $S_1 \sqcup S_2 = S_1 \cup S_2$ and their intersection as $S_1 \sqcap S_2 = \{C_1 \cup C_2 \mid C_1 \in S_1, C_2 \in S_2\}$.

DEFINITION C.2. *Given a constraint-set $C \subseteq C$, the set of type row and field variables occurring in C is defined as $\text{vars}(C) = \bigcup_{(T_1, c, T_2) \in C} \text{vars}(T_1) \cup \text{vars}(T_2)$, with $\text{vars}(T_i)$ defined in Definition B.2.*

DEFINITION C.3 (ORDERING). *Let V and Δ be sets of variables and L a set of labels. An ordering O_X on V is an injective map from V to \mathbb{N} , an ordering O_{ℓ} on L is an injective map from L to \mathbb{N} . An*

ordering O on V and L is defined as a lexicographic ordering on $\mathbb{N} \times \mathbb{N}$ according to O_X and O_ℓ , where: $O(\rho.\ell) = (O_X(\rho), O_\ell(\ell))$, $O(\rho \setminus L) = (O_X(\rho), O'(\rho, L))$ and $O(X) = (O_X(X), 0)$ otherwise; for all $X_1 \notin \Delta$ and $X_2 \in \Delta$ of the same kind, $O(X_1) < O(X_2)$; and $O'(\rho, L)$ is an integer obtained in a canonical way from the set $L \cup \text{def}(\rho)$ and different from any $O_\ell(\ell)$.

DEFINITION C.4 (DECOMPOSITION OF ROW VARIABLES). We introduce two new constructors: (1) $\rho.\ell$, that we treat as a field variable, and (2) $\rho \setminus L$, that we treat as a row variable of definition space $\text{def}(\rho) \setminus L$. Substitution is extended to $(\rho.\ell)\sigma = \tau$ if $\sigma(\rho) \simeq \langle \ell = \tau \mid r \rangle^{L'}$, and $(\rho \setminus L)\sigma = r$ if $\sigma(\rho) \simeq \langle (\ell = \tau_\ell)_{\ell \in L \cap \text{def}(\rho)} \mid r \rangle^{L'}$. It is undefined if $\sigma(\rho)$ does not have any of these shapes.

Hereafter, the name ρ ranges over row variables and constructors $\rho \setminus L$, the name θ ranges over field variables and constructors $\rho.\ell$, and the name X ranges over all kinds of variables plus these new constructors. We consider $\rho \setminus L$ up to the equivalence generated by identifying $\rho \in \mathcal{V}_r$ with $\rho \setminus L$ for all $L \subseteq \mathcal{L} \setminus \text{def}(\rho)$, and $(\rho \setminus L_1) \setminus L_2$ with $\rho \setminus (L_1 \cup L_2)$. With an abuse of notation we write ρ for the row $\langle \mid \rho \rangle^{\mathcal{L} \setminus \text{def}(\rho)}$ —in particular in rows constraints (e.g., (ρ, c, r))—when no confusion arises.

DEFINITION C.5 (CONSTRAINT SOLUTION). Let $C \subseteq \mathcal{C}$ be a constraint-set. A solution to C is a substitution σ such that $\forall (T_1, \leq, T_2) \in C. T_1\sigma \leq T_2\sigma$ and $\forall (T_1, \geq, T_2) \in C. T_1\sigma \geq T_2\sigma$ hold. If σ is a solution to C , we write $\sigma \models C$. In particular, $T_1\sigma$ and $T_2\sigma$ must be defined, that is, for all $\rho \in \text{dom}(\sigma)$:

- $\forall \ell \in \mathcal{L}. \rho.\ell \in \text{vars}(C) \implies \exists \tau. \exists r. \sigma(\rho) \simeq \langle \ell = \tau \mid r \rangle^{\mathcal{L} \setminus \text{def}(\rho)}$, and
- $\forall L \subseteq \mathcal{L}. \rho \setminus L \in \text{vars}(C) \implies \exists (\tau_\ell)_{\ell \in L}. \exists r. \sigma(\rho) \simeq \langle (\ell = \tau_\ell)_{\ell \in L} \mid r \rangle^{\mathcal{L} \setminus \text{def}(\rho)}$.

where $\text{vars}(C)$ is the set of all type/row/field variables occurring in C .

The tallying algorithm is parametric on a total order O on variables, used to ensure that the step (5) of tallying produces contractive types (see [Proposition 3.8](#)). A set of constraints is *well-ordered* if for all constraints of the shape (X, c, T) and for all variables in T that are not occurring under a type constructor, $O(X) < O(X')$ holds (we call such variables the *toplevel variables* of T).

C.1 Examples Regarding the Restriction of Solutions to Atomic Rows

We give two examples where we discuss considering only atomic rows instead of Boolean combinations of them in the grammar. The first one shows that we can find tallying solutions even for unions of records thanks to the unification technique. The second demonstrates that this technique is not enough to recover all desired solutions, and therefore that Boolean combinations of rows, as we adopt them in our system, are welcome.

Example C.1. Let us consider the types of the example on [Page 5](#), that we rewrite as follows: $t_1 = \{p = \text{Int} \mid \rho\} \rightarrow \{p = \text{Float} \mid \rho\}$ and $t_2 = \{s = \text{"circle"}, p = \text{Int}, d = \text{Float} \mid \epsilon\} \vee \{s = \text{"polygon"}, p = \text{Int}, e = \text{Int} \mid \epsilon\}$. We would like to be able to unify the parameter of the function with the argument, even though the latter is a union. As explained in [[10](#), §C.2.1], the problem of computing $t_1 \bullet_\theta t_2$ can be reduced to solving $\{(t', \leq, t_2 \rightarrow \alpha)\}$, where α is a fresh variable, and $t' = \bigwedge_{i \in I} t_1 \sigma_i$, where the σ_i are renamings of ρ . The cardinality of I will be increased during the search for a solution.

With a cardinality $|I| = 1$, we need in particular to find a solution for the constraint $(\{p = \text{Int} \mid \rho\}, \geq, t_2)$. A component-wise unification gives the most precise solution (since we restrict ourselves to atomic rows): $\sigma(\rho) = \{s = \text{"circle"} \vee \text{"polygon"}, d = \text{Float} \vee \perp, e = \text{Int} \vee \perp \mid \epsilon\}^{\{s\}}$.

This is however not the solution we want. Incrementing the cardinality of I , we now look for a solution of $\{(\{p = \text{Int} \mid \rho_1\} \rightarrow \{p = \text{Int} \mid \rho_1\}) \wedge (\{p = \text{Int} \mid \rho_2\} \rightarrow \{p = \text{Int} \mid \rho_2\}), \leq, t_2 \rightarrow \alpha\}$. Thus, we look in particular for a solution to the constraint $(\{p = \text{Int} \mid \rho_1\} \vee \{p = \text{Int} \mid \rho_2\}, \geq, t_2)$. A component-wise unification gives the solution $\sigma(\rho_1) = \{s = \text{"circle"}, d = \text{Float} \mid \epsilon\}^{\{s\}}$, $\sigma(\rho_2) = \{s = \text{"polygon"}, e = \text{Int} \mid \epsilon\}^{\{s\}}$, thanks to which we retrieve the desired solution, even with the restriction that rows are all atomic.

Example C.2 (Necessity of connectives on rows). This second examples illustrates why considering only atomic rows is not satisfactory. Take $t = \{\mid \rho\} \rightarrow \{\mid \rho\}$ and $s = \{a = \perp \mid \dots\} \wedge \neg\{\mid \epsilon\}$ and let us look for a solution of $t \bullet_0 s$. As in the previous example, this problem can be reduced to solving $\{(t', \leq, s \rightarrow \alpha)\}$, where α is a fresh variable, and $t' = \bigwedge_{i \in I} t \sigma_i$, where the σ_i are renamings of ρ .

At first, we try $|I| = 1$, so we look for a solution of $\{(\{\mid \rho\} \rightarrow \{\mid \rho\}, \leq, \{a = \perp \mid \dots\} \wedge \neg\{\mid \epsilon\} \rightarrow \alpha)\}$. After normalization, we obtain the constraint-set $\{(\alpha, \geq, \{\mid \rho\}), (\rho, \geq, \langle a = \perp \mid \dots \rangle^0 \wedge \neg\langle \mid \epsilon \rangle^0)\}$. If we were to consider only atomic rows, we could only give the solution $\sigma(\rho) = \langle \mid \dots \rangle^0$ and $\sigma(\alpha) = \{\mid \dots\}$.

To try to find a more precise solution, we run tallying again after incrementing the cardinal of I . This yields the following constraint-set: $\{(\{\mid \rho_1\} \rightarrow \{\mid \rho_1\}) \wedge (\{\mid \rho_2\} \rightarrow \{\mid \rho_2\}), \leq, s \rightarrow \alpha)\}$, which normalizes first to $\{(\alpha, \geq, \{\mid \rho_1\} \wedge \{\mid \rho_2\}), (\rho_1 \vee \rho_2, \geq, \langle a = \perp \mid \dots \rangle^0 \wedge \neg\langle \mid \epsilon \rangle^0)\}$, and then (assuming $O(\rho_1) \leq O(\rho_2)$) to $\{(\alpha, \geq, \{\mid \rho_1\} \wedge \{\mid \rho_2\}), (\rho_1, \geq, \langle a = \perp \mid \dots \rangle^0 \wedge \neg\langle \mid \epsilon \rangle^0 \wedge \neg\rho_2)\}$. With atomic rows only, we still do not have a satisfactory solution, and further expansions do not help.

C.2 General Decomposition of Rows

DEFINITION C.6. Let $r = \langle (\ell = \tau_\ell)_{\ell \in L_1} \mid \zeta \rangle^{L_2}$ and L a finite set of labels. We define $r \setminus L = \langle (\ell = \tau_\ell)_{\ell \in L_1 \setminus L} \mid \zeta' \rangle^{L_2 \cup L}$, where $\zeta' = \dots$ if $\zeta \in \mathcal{V}$ and $L \not\subseteq L_1 \cup L_2$, and $\zeta' = \zeta$ otherwise.

LEMMA C.3. Let r be an atomic row and L a set of labels. Let $r' = \langle L \cap \text{lab}(r) \mid r \setminus (L \cap \text{lab}(r)) \rangle$ if $\text{tail}(r) = \rho$ and $\text{def}(\rho) \cap L \neq \emptyset$, and $r' = \langle L \mid r \setminus L \rangle$ otherwise.

- (1) $r \simeq \langle (\ell = r(\ell))_{\ell \in L} \mid \dots \rangle \wedge r' \simeq \bigwedge_{\ell \in L} \langle \ell = r(\ell) \mid \dots \rangle \wedge r'$
- (2) $\langle L \cap \text{lab}(r) \mid r \setminus (L \cap \text{lab}(r)) \rangle \simeq \langle L \mid r \setminus L \rangle \wedge \langle \text{lab}(r) \mid \text{tail}(r) \rangle$ if $\text{tail}(r) \in \mathcal{V}$.

PROOF. If $r' = \langle L \mid r \setminus L \rangle$, the proof is straightforward. Otherwise, let $r = \langle (\ell = \tau_\ell)_{\ell \in L_1} \mid \rho \rangle^{L_2}$, with $L \not\subseteq L_1 \cup L_2$. For the first item, since $r(\ell) = \mathbb{1} \vee \perp$ for any $\ell \notin L_1 \cap L_2$, we must show $r \simeq \langle (\ell = \tau_\ell)_{\ell \in L \cap L_1}, (\ell = \mathbb{1} \vee \perp)_{\ell \in L \setminus L_1} \mid \dots \rangle \wedge \langle L \cap L_1, (\ell = \tau_\ell)_{\ell \in L_1 \setminus L} \mid \rho \rangle$. For the second item, we must show $\langle L \cap L_1, (\ell = \tau_\ell)_{\ell \in L_1 \setminus L} \mid \rho \rangle \simeq \langle L, (\ell = \tau_\ell)_{\ell \in L_1 \setminus L} \mid \dots \rangle \wedge \langle \text{lab}(r) \mid \rho \rangle$. Both of them are straightforward. \square

LEMMA C.4. Let P and N be sets of atomic rows of the same definition space and L be a finite set of labels. Let $P_{\mathcal{V}} = \{r \in P \mid \text{tail}(r) = \rho \text{ and } L \cap \text{def}(\rho) \neq \emptyset\}$, similarly for $N_{\mathcal{V}}$. The relation $\bigwedge_{r \in P} r \leq \bigvee_{r \in N} r$ holds iff for every map $\iota : N \rightarrow L \cup \{_ \}$, for every $N' \subseteq \iota^{-1}(_) \cap N_{\mathcal{V}}$:

$$\left(\exists \ell \in L. \bigwedge_{r \in P} r(\ell) \leq \bigvee_{r \in \iota^{-1}(\ell)} r(\ell) \right) \text{ or } \left(\bigwedge_{r \in P} r \setminus L \leq \bigvee_{r \in \iota^{-1}(_) \cap N'} r \setminus L \right) \\ \text{ or } \left(\bigwedge_{r \in P_{\mathcal{V}}} \langle \text{lab}(r) \mid \text{tail}(r) \rangle \leq \bigvee_{r \in N'} \langle \text{lab}(r) \mid \text{tail}(r) \rangle \right)$$

PROOF. For each $r \in P_{\mathcal{V}} \cup N_{\mathcal{V}}$, let $r_- = \langle L \cap \text{lab}(r) \mid r \setminus (L \cap \text{lab}(r)) \rangle$ and for each $r \in (P \cup N) \setminus (P_{\mathcal{V}} \cup N_{\mathcal{V}})$, let $r_- = \langle L \mid r \setminus L \rangle$.

Using **Lemma C.3**, we decompose the type in the statement into:

$$\bigwedge_{r \in P} (\langle (\ell = r(\ell))_{\ell \in L} \mid \dots \rangle \wedge r_- \wedge \bigwedge_{r \in N} (\bigvee_{\ell \in L} \neg \langle \ell = r(\ell) \mid \dots \rangle \vee \neg r_-)) \quad (17)$$

We can distribute the intersection of the elements of N on the right of (17) over the unions in the second brackets. We obtain a union of intersections of, each time, $|N|$ elements, where each intersection is a possible combination of the individual types present in the second line. Each combination is described by a function $\iota : N \rightarrow L \cup \{_ \}$, where $\iota(n) = \ell$ means that the element $\langle \ell = r(\ell) \mid \dots \rangle$ is present in the combination given by ι , while $\iota(n) = _$ means that the element $\neg r_-$

is present in the combination. For each $r \in N$ and $\ell \in L$, let us write $r_\ell = \langle \ell = r(\ell) \mid \dots \rangle$. Therefore the type in (17) is equivalent to:

$$\bigwedge_{r \in P} (\langle (\ell = r(\ell))_{\ell \in L} \mid \dots \rangle \wedge r_-) \wedge \bigvee_{\iota : N \rightarrow L \cup \{_ \}} \left(\bigwedge_{r \in N} \neg r_{\iota(r)} \right) \quad (18)$$

By distributing the intersection over the union we obtain

$$\bigvee_{\iota : N \rightarrow L \cup \{_ \}} \left(\bigwedge_{r \in P} (\langle (\ell = r(\ell))_{\ell \in L} \mid \dots \rangle \wedge r_-) \wedge \bigwedge_{r \in N} \neg r_{\iota(r)} \right) \quad (19)$$

A union is empty if and only if each summand of the union is empty. Therefore the type above is empty if and only if for all $\iota : N \rightarrow L \cup \{_ \}$, the following type is empty:

$$\begin{aligned} & \bigwedge_{r \in P} (\langle (\ell = r(\ell))_{\ell \in L} \mid \dots \rangle \wedge r_-) \wedge \bigwedge_{r \in N} \neg r_{\iota(r)} \\ & \simeq \bigwedge_{r \in P} (\langle (\ell = r(\ell))_{\ell \in L} \mid \dots \rangle \wedge r_-) \wedge \bigwedge_{\ell \in L \cup \{_ \}} \bigwedge_{r \in \iota^{-1}(\ell)} \neg r_\ell \\ & \simeq \bigwedge_{r \in P} (\langle (\ell = r(\ell))_{\ell \in L} \mid \dots \rangle \wedge r_-) \wedge \bigwedge_{r \in \iota^{-1}(_)} \neg r_- \wedge \bigwedge_{\ell \in L} \bigwedge_{r \in \iota^{-1}(\ell)} \neg r_\ell \\ & \simeq \bigwedge_{r \in P} (\langle (\ell = r(\ell))_{\ell \in L} \mid \dots \rangle \wedge r_-) \wedge \bigwedge_{r \in \iota^{-1}(_)} \neg r_- \wedge \langle (\ell = \bigwedge_{r \in \iota^{-1}(\ell)} \neg r(\ell))_{\ell \in L} \mid \dots \rangle \\ & \simeq \langle (\ell = \bigwedge_{r \in P} r(\ell) \wedge \bigwedge_{r \in \iota^{-1}(\ell)} \neg r(\ell))_{\ell \in L} \mid \dots \rangle \wedge \bigwedge_{r \in P} r_- \wedge \bigwedge_{r \in \iota^{-1}(_)} \neg r_- \end{aligned}$$

Let $r_1 = \langle (\ell = \bigwedge_{r \in P} r(\ell) \wedge \bigwedge_{r \in \iota^{-1}(\ell)} \neg r(\ell))_{\ell \in L} \mid \dots \rangle$. The last type is equivalent to

$$\begin{aligned} & r_1 \wedge \bigwedge_{r \in P} \langle L \mid r \setminus L \rangle \wedge \bigwedge_{r \in P_V} \langle \text{lab}(r) \mid \text{tail}(r) \rangle \\ & \wedge \bigwedge_{r \in \iota^{-1}(_)\setminus N_V} \neg \langle L \mid r \setminus L \rangle \wedge \bigwedge_{r \in \iota^{-1}(_)\cap N_V} (\neg \langle L \mid r \setminus L \rangle \vee \neg \langle \text{lab}(r) \mid \text{tail}(r) \rangle) \\ & \simeq r_1 \wedge \bigwedge_{r \in P} \langle L \mid r \setminus L \rangle \wedge \bigwedge_{r \in P_V} \langle \text{lab}(r) \mid \text{tail}(r) \rangle \wedge \bigwedge_{r \in \iota^{-1}(_)\setminus N_V} \neg \langle L \mid r \setminus L \rangle \\ & \wedge \bigvee_{N' \subseteq \iota^{-1}(_)\cap N_V} \left(\bigwedge_{r \in (\iota^{-1}(_)\cap N_V) \setminus N'} \neg \langle L \mid r \setminus L \rangle \wedge \bigwedge_{r \in N'} \neg \langle \text{lab}(r) \mid \text{tail}(r) \rangle \right) \\ & \simeq \bigvee_{N' \subseteq \iota^{-1}(_)\cap N_V} \left(r_1 \wedge \bigwedge_{r \in P} \langle L \mid r \setminus L \rangle \wedge \bigwedge_{r \in \iota^{-1}(_)\setminus N'} \neg \langle L \mid r \setminus L \rangle \right. \\ & \quad \left. \wedge \bigwedge_{r \in P_V} \langle \text{lab}(r) \mid \text{tail}(r) \rangle \wedge \bigwedge_{r \in N'} \neg \langle \text{lab}(r) \mid \text{tail}(r) \rangle \right) \end{aligned}$$

This type is empty if and only if the conjunctions are all empty for each ι and $N' \subseteq \iota^{-1}(_)\cap N_V$. Take ι and N' and let $r_2 = \bigwedge_{r \in P} \langle L \mid r \setminus L \rangle \wedge \bigwedge_{r \in \iota^{-1}(_)\setminus N'} \neg \langle L \mid r \setminus L \rangle$ and $r_3 = \bigwedge_{r \in P_V} \langle \text{lab}(r) \mid \text{tail}(r) \rangle \wedge \bigwedge_{r \in N'} \neg \langle \text{lab}(r) \mid \text{tail}(r) \rangle$. Let $r_i = \bigwedge_{1 \leq i \leq 3} r_i$. It is immediate that r_1 is empty *iff* the first condition of the statement holds, r_2 is empty *iff* the second does, and r_3 is empty *iff* the third does. We directly obtain that if one of the conditions holds, then the type r_i is empty. We now show that if r_i is empty, then there is $1 \leq i \leq 3$ such that r_i is empty.

For this, we suppose that none of the subtypes is empty and build an element $\mathfrak{d} \in \llbracket r_i \rrbracket^{\text{row}}$.

- (1) Since r_1 is not empty, for all $\ell \in L$ there is an element $\delta_\ell^1 \in \llbracket \bigwedge_{r \in P} r(\ell) \wedge \bigwedge_{r \in I^{-1}(\ell)} \neg r(\ell) \rrbracket^{\text{fld}}$.
- (2) Since r_2 is not empty, there is an element $\langle (\ell = \delta_\ell^2)_{\ell \in L_2}, _ = \perp^0 \rangle^{V_2} \in \llbracket r_2 \rrbracket^{\text{row}}$.
- (3) Since r_3 is not empty, there is an element $\vec{d}_3 \in \llbracket r_3 \rrbracket^{\text{row}}$. However, the restrictions on the set of elements in $\llbracket r_3 \rrbracket^{\text{row}}$ only concern their tags so that any element \vec{d}' with $\text{tag}(\vec{d}') = \text{tag}(\vec{d}_3)$ and $\text{def}(\vec{d}') = \text{def}(\vec{d}_3)$ is in $\llbracket r_3 \rrbracket^{\text{row}}$. Let $V_3 = \text{tag}(\vec{d}_3)$.

We build the element $\langle (\ell = \delta_\ell^1)_{\ell \in L}, (\ell = \delta_\ell^2)_{\ell \in L_2 \setminus L}, _ = \perp^0 \rangle^{V_3}$. This element belongs to $\llbracket r_1 \rrbracket^{\text{row}}$, which is a contradiction. \square

C.3 Explanation of Normalization of Constraints

Before giving a formal description of the whole normalization algorithm as inference rules in [Appendix C.4](#), we describe it as a recursive function $\text{norm}(t, M)$ that takes a type t as input and returns a set of normalized constraint-sets necessary for $t \leq \mathbb{0}$ to hold. The additional argument M is a set of visited types, that guarantees termination of recursion on infinitary types. We consider the implicit constant parameter Δ containing the monomorphic variables.

We first rewrite each constraint (T, c, T') into a set of constraints $\{(T_i, \leq, \mathbb{0})\}_{i \in I}$, where T_i is a conjunction of atoms (basic types, arrows, records), type and field variables (in the latter case, \perp can also be present), or their negations. This first constraint-set is obtained by transforming the type into DNF and putting each summand of the outer union into a separate constraint. For each constraint $(T_i, \leq, \mathbb{0})$ we then isolate the smallest (w.r.t., the order O) top-level type variable or field variable X not in Δ , to obtain a constraint of the form (X, c, T'_i) , that gives a lower (i.e., c is \geq when X is negated in T_i) or an upper (i.e., c is \leq otherwise) bound on that variable, where T'_i is obtained from T_i simply by removing X .

There may be no variable in T_i , or they may all be in the parameter Δ . A variable in Δ is monomorphic, cannot be instantiated and is treated as a constant. In that case, we erase monomorphic variables because they cannot help to satisfy the constraint. On basic types, we can directly see if the constraint holds. For arrow constructors, we apply subtyping to decompose the types into constraints on their subtypes. Until now, all these steps (apart from dealing with field variables) are similar to those of the existing tallying algorithm for type variables by Castagna et al. [10]. For a conjunction of record atoms, the technique is more elaborated.

The normalization of a conjunction of records t is defined as the normalization of its underlying row through an auxiliary procedure on rows:

$$\text{norm}(t, M) = \text{norm}_{\text{row}}(\text{row}(t), M \cup \{t\})$$

The main technical part of the normalization step of tallying is defining this auxiliary procedure. It uses the following two operators.

DEFINITION C.7. Let $r = \langle (\ell = \tau_\ell)_{\ell \in L_1} \mid \zeta \rangle^{L_2}$, Δ be a set of variables, $\ell \in \mathcal{L} \setminus L_2$ and $L \in \mathcal{P}_{\text{fin}}(\mathcal{L})$.

- $r[\ell] \stackrel{\text{def}}{=} \rho.\ell$ if $\zeta = \rho \notin \Delta$ and $\ell \in \text{def}(\rho)$, and $r[\ell] \stackrel{\text{def}}{=} r(\ell)$ otherwise.
- $\langle (\ell = \tau_\ell)_{\ell \in L_1} \mid \zeta \rangle^{L_2 \setminus \Delta L} \stackrel{\text{def}}{=} \langle (\ell = \tau_\ell)_{\ell \in L_1 \setminus L} \mid \zeta' \rangle^{L_2 \cup L}$; where if $\zeta = \rho$ and $\text{def}(\rho) \cap L \neq \emptyset$: $\zeta' = ..$ if $\rho \in \Delta$ and $\zeta' = \rho \setminus L$ otherwise; and $\zeta' = \zeta$ otherwise.

Let us consider a row in DNF $r_0 = \bigwedge_{r \in P} r \wedge \bigwedge_{r \in N} \neg r$. Let ρ_0 be the smallest top-level variable of r_0 not in Δ and $L = \text{def}(r_0) \setminus \text{def}(\rho_0)$, or $L = \emptyset$ if no such variable exists. Let $S_\Delta = \{r \in S \mid \text{tail}(r) = \rho \in \Delta \text{ and } \text{def}(\rho) \cap L \neq \emptyset\}$, for $S = P, N$. Normalization $\text{norm}_{\text{row}}(r_0, M)$ is defined as:

$$\prod_{\iota: N \rightarrow L \cup \{_ \}} \left(\bigsqcup_{\ell \in L} \text{norm}_{\text{fld}} \left(\bigwedge_{r \in P} r[\ell] \wedge \bigwedge_{r \in I^{-1}(\ell)} \neg r[\ell], M \right) \sqcup \prod_{N' \in \mathcal{N}} \left(\text{norm}_{\text{tl}} \left(\bigwedge_{r \in P} (r \setminus^\Delta L) \wedge \bigwedge_{r \in I^{-1}(_) \setminus N' \in S} \neg (r \setminus^\Delta L), M \right) \right) \right)$$

where $\mathcal{N} = \{N' \subseteq \iota^{-1}(_) \cap N_\Delta \mid \bigwedge_{r \in P_\Delta} \langle \text{lab}(r) \mid \text{tail}(r) \rangle \not\leq \bigvee_{r \in N'} \langle \text{lab}(r) \mid \text{tail}(r) \rangle\}$.

Here, the idea of the algorithm is the following. If there is no polymorphic top-level variable (these can only be row variables), we let $L = \emptyset$, which does not decompose the row, and only calls the function $\text{norm}_{\text{fl}}(r_0, M)$ recursively. This function decomposes the record over the whole set of top-level labels using the formula for subtyping. We do not loose solutions doing so: due to the absence of top-level polymorphic variables, the emptiness of r_0 can only be satisfied by the emptiness of one of the components.

If there is a smallest polymorphic top-level variable ρ_0 , we take $L = \text{def}(r_0) \setminus \text{def}(\rho_0)$. In other words, we take L to be the set of labels on the left of the variable ρ_0 . In this way, we decompose the row on one side over the elements in L , which does not affect ρ_0 . These elements are handled by the auxiliary function norm_{fld} , that normalizes constraints on fields in a way similar to what is done on types. On the other side, we obtain constraints over ρ_0 , where ρ_0 is in a row of the shape $\langle \mid \rho_0 \rangle^{\mathcal{L} \setminus \text{def}(\rho_0)}$. Then, the recursive call to norm_{fl} singles out the variable ρ_0 in order to obtain an upper or lower bound for ρ_0 , as we do for type and field variables (the definitions of norm_{fld} and norm_{fl} are given below).

While ρ_0 is not affected by the decomposition thanks to our choice of L , there can be polymorphic top-level variables ρ' such that $\text{def}(\rho') \cap L \neq \emptyset$. This is why we have introduced the two new operators $r[\ell]$ and $r \setminus^\Delta L$.

Fields. A field-type is always equivalent to a DNF that is a disjunction of conjunctions of either of the shape $\tau \wedge \bigwedge_{\theta \in P} \theta \wedge \bigwedge_{\theta \in N} \theta$, where τ is either \perp or a type t . If there is a smallest variable $\theta_0 \in P \cup N$ not in Δ , we single out this variable, in the same way as is done for type variables in our algorithm and in [10]. If all top-level field variables are monomorphic:

- If $\tau = t$, τ can be instantiated to an empty type only if t can, so we apply $\text{norm}(t, M)$.
- If $\tau = \perp$, τ can never be instantiated to an empty type since $\perp \not\leq \emptyset$, so normalization fails.

We use the notation $X \not\leq T$ to indicate that X is the smallest top-level variable in T .

$$\text{norm}_{\text{fld}}(\tau, M) = \begin{cases} \{ \{ (\theta_0, \leq, \neg\tau \vee \bigvee_{\theta \in P \setminus \{\theta_0\}} \neg\theta \vee \bigvee_{\theta \in N} \theta) \} \}, & \text{if } \exists \theta_0 \in P. \theta_0 \not\leq \tau \\ \{ \{ (\tau \wedge \bigwedge_{\theta \in P} \theta \wedge \bigwedge_{\theta \in N \setminus \{\theta_0\}} \neg\theta \leq \theta_0) \} \}, & \text{if } \exists \theta_0 \in N. \theta_0 \not\leq \tau \\ \text{norm}(t, M), & \text{if } \tau' = t \text{ and } (P \cup N) \setminus \Delta = \emptyset \\ \emptyset, & \text{if } \tau' = \perp \text{ and } (P \cup N) \setminus \Delta = \emptyset \end{cases}$$

Tails. By design, the input of this function is a row such that:

- Either there is a polymorphic top-level variable that is an a row r_0 with $\text{lab}(r) = \emptyset$. Then, we single out this variable on the left of a new constraint.
- Or there is no polymorphic top-level row variable. In that case, we decompose the row over all the labels using the subtyping formula.

$$\text{norm}_{\text{fl}}(r, M) = \begin{cases} \{ \{ (\rho_0, \leq, \bigvee_{r \in P \setminus \{r_0\}} \neg r \vee \bigvee_{r \in N} r) \} \}, & \text{if } r_0 \in P \\ \{ \{ (\rho_0, \geq, \bigwedge_{r \in P} r \wedge_{r \in N \setminus \{\rho\}} \neg r) \} \}, & \text{if } r_0 \in N \\ \left(\prod_{l \in I} \sqcup_{\ell \in L} \text{norm}_{\text{fld}} \left(\bigwedge_{r \in P} r(\ell) \wedge \bigwedge_{r \in I^{-1}(\ell)} \neg r(\ell), M \right) \right), & \text{if } \text{tlv}(r) \subseteq \Delta \end{cases}$$

where in the two first cases, there is $\rho_0 \in (P \cup N) \setminus \Delta$ such that there is $r_0 \in P \cup N$ with $r_0 = \langle \mid \rho_0 \rangle^{\mathcal{L} \setminus \text{def}(r)}$, and where in the last case:

- $L = \bigcup_{r \in P \cup N} \text{lab}(r)$;
- $P_\Delta = \{r \in P \mid \text{tail}(r) \in \mathcal{V}\}$ and $N_\Delta = \{r \in N \mid \text{tail}(r) \in \mathcal{V}\}$;
- $I = \{l : N \rightarrow L \cup \{_ \} \mid (\forall r_\circ \in I^{-1}(_) \setminus N_\Delta. \bigwedge_{r \in P} \text{def}(r) \not\leq \text{def}(r_\circ)) \text{ and } (\forall r_\circ \in I^{-1}(_) \cap N_\Delta. \forall r_p \in P_\Delta. \text{tail}(r_\circ) \neq \text{tail}(r_p))\}$, where $\text{def}(r)$ is defined as in Lemma A.6.

Fig. 6. Normalization rules for type and field single normal forms

C.4 Constraint Normalization

We formalize normalization as a judgment $\Sigma \vdash_N C \rightsquigarrow \mathcal{S}$, which states that under the environment Σ (which, informally, contains the types that have already been processed at this point), C is normalized to \mathcal{S} . The main judgment is derived according to the rules in Figs. 5 to 7. Given a type, field or row variable X and a conjunction of types, field-types or rows respectively, we define $\text{single}(X, T \wedge X) = \{(X, \leq, \neg T)\}$ and $\text{single}(X, T \wedge \neg X) = \{(X, \geq, T)\}$. We call single normal form a DNF that has no topmost disjunction.

If $\emptyset \vdash_N C \rightsquigarrow \mathcal{S}$, then \mathcal{S} is the result of the normalization of C . We now prove soundness and termination of the constraint normalization algorithm.

DEFINITION C.8. We define the family $(\leq_n)_{n \in \mathbb{N}}$ of subtyping relations as

$$t \leq_n s \stackrel{\text{def}}{\iff} \forall \eta. \llbracket t \rrbracket_n \eta \subseteq \llbracket s \rrbracket_n \eta$$

where $\llbracket \cdot \rrbracket_n$ is the rank n interpretation of a type, defined as

$$\llbracket t \rrbracket_n \eta = \{d \in \llbracket t \rrbracket_\eta \mid \text{height}(d) \leq n\}$$

and $\text{height}(d)$ is the height of an element in \mathcal{D} , defined as

...

$$\text{height}(\text{Rec}(\vec{d})^V) = 1 + \text{height}(\vec{d})$$

$$\text{height}(\langle \ell = \delta_\ell \rangle_{\ell \in L, _} = \perp^0 \rangle_{L'}^V) = \max(1, (\text{height}(\delta_\ell))_{\ell \in L})$$

LEMMA C.5. Let $t \leq \{\mid \cdot\}$. Then, $t \leq_{n+1} \emptyset \iff \text{row}(t) \leq_n \emptyset$.

PROOF. By definition and a trivial well-founded induction on type operators, we have $\llbracket t \rrbracket_n^q = \{\text{Rec}(\vec{d})^V \mid \vec{d} \in \llbracket \text{row}(t) \rrbracket_n^q\}$. Thus, by definition of height, we have $\llbracket t \rrbracket_{n+1}^q = \{\text{Rec}(\vec{d})^V \mid \vec{d} \in \llbracket \text{row}(t) \rrbracket_n^q\}$. \square

DEFINITION C.9. Given a constraint-set C and a substitution σ , we define the rank n satisfaction predicate \Vdash_n as

$$\sigma \Vdash_n C \stackrel{\text{def}}{\iff} \forall (T_1, \leq, T_2) \in C. T_1 \leq_n T_2 \text{ and } \forall (T_1, \geq, T_2) \in C. T_1 \geq_n T_2$$

LEMMA C.6. (1) $\sigma \Vdash_0 C$ for all σ and C .

(2) $\sigma \Vdash C \iff \forall n. \sigma \Vdash_n C$.

PROOF. Consequence of [10, Lemma C.7] and Lemma C.5. \square

DEFINITION C.10 (MARSHALLING). Given a conjunction of atomic rows $r_0 = \bigwedge_{r \in P} r \wedge \bigwedge_{r \in N} r$, a finite set of labels and a set of variables, we define marshalling as

$$\text{marsh}(r, L, \Delta) = \bigwedge_{r \in P \setminus P_0} r \wedge \bigwedge_{r \in N \setminus N_0} \neg r \wedge \bigwedge_{r \in P_0} \langle (\ell = r[\ell])_{\ell \in L} \mid r \setminus^\Delta L \rangle \wedge \bigwedge_{r \in N_0} \neg \langle (\ell = r[\ell])_{\ell \in L} \mid r \setminus^\Delta L \rangle$$

where $P_0 = \{r \in P \mid \text{tail}(r) = \rho \notin \Delta \text{ and } \text{def}(\rho) \cap L \neq \emptyset\}$, similarly for N_0 .

LEMMA C.7. If $\sigma \Vdash \{(\text{marsh}(r, L, \Delta), \leq, \emptyset)\}$, then $\sigma \Vdash \{(r, \leq, \emptyset)\}$.

PROOF. We show that $\text{marsh}(r_0, L, \Delta)\sigma = r_0\sigma$. Let $r = \langle (\ell = r(\ell))_{\ell \in L_1} \mid \rho \rangle \in P_0 \cup N_0$ and $r' = \langle (\ell = r[\ell])_{\ell \in L} \mid r \setminus^\Delta L \rangle$. Then, $r' = \langle (\ell = r(\ell))_{\ell \in L_1}, (\ell = \rho.\ell)_{\ell \in L \setminus L_1} \mid \rho \setminus L \rangle$. We have $\sigma(\rho) \simeq \langle (\ell = \tau_\ell)_{\ell \in L \setminus L_1} \mid r'' \rangle^{\mathcal{L} \setminus \text{def}(\rho)}$ because σ is a solution for $\{(\text{marsh}(r_0, L, \Delta), \leq, \emptyset)\}$. Therefore, $r\sigma = \text{marsh}(r, L, \Delta)\sigma$. \square

Given a set Σ of types and rows, we write $C(\Sigma)$ for the constraint-set $\{(T, \leq, \emptyset) \mid T \in \Sigma\}$.

LEMMA C.8 (SOUNDNESS). *Let C be a constraint-set. If $\emptyset \vdash_N C \rightsquigarrow \mathcal{S}$, then for all constraint-set $C' \in \mathcal{S}$ and all substitution σ , we have $\sigma \Vdash C' \implies \sigma \Vdash C$.*

PROOF. We prove the following stronger statements.

(1) Assume $\Sigma \vdash_N C \rightsquigarrow \mathcal{S}$. For all $C' \in \mathcal{S}$, σ and n , if $\sigma \Vdash_n C(\Sigma)$ and $\sigma \Vdash_n C'$, then $\sigma \Vdash_n C$.

(2) Assume $\Sigma \vdash_{N^*} C \rightsquigarrow \mathcal{S}$. For all $C' \in \mathcal{S}$, σ and n , if $\sigma \Vdash_n C(\Sigma)$ and $\sigma \Vdash_n C'$, then $\sigma \Vdash_{n+1} C$.

The cases (NEMPTY), (NJOIN), (NSYM), (NZERO), (NDNF), (NUNION), (NHYP), (NASSUM), (NBASIC) and (NARROW) are given in [10, Lemma C.10].

(NTLV) Let $T_0 = T \wedge \bigwedge_{X \in P} X \wedge \bigwedge_{X \in N} \neg X$ and X' be the smallest type variable with respect to the order in $P \cup N$. If $X' \in P \setminus \Delta$, then we have $\sigma \Vdash_n \{(X', \leq, \neg T_{X'})\}$ with $T_{X'} = T \wedge \bigwedge_{X \in P, X \neq X'} X \wedge \bigwedge_{X \in N} \neg X$, thus $(X')\sigma \leq_n \neg T_{X'}\sigma$. This is equivalent to $T\sigma \leq_n \emptyset$, and we conclude $\sigma \Vdash_n \{(T, \leq, \emptyset)\}$. If $X' \in N \setminus \Delta$, the result follows as well. If $X' \in \Delta$, then $P \cup N \subseteq \Delta$ by Definition C.3. We have $\llbracket T_0 \rrbracket = \{D \in \llbracket T \rrbracket \mid P \subseteq \text{tag}(D) \text{ and } N \cap \text{tag}(D) = \emptyset\}$. Since T_0 is non empty, the variables in P and N are different, and since those variables cannot be instantiated, we can satisfy $T_0 \leq \emptyset$ if and only if $T \leq \emptyset$ is satisfied.

(NOPT) Direct by emptiness of \mathcal{S} .

(NREC) Let $t = \bigwedge_{R \in P} R \wedge \bigwedge_{R \in N} \neg R$. By induction, we have $\sigma \Vdash_n \{(\text{row}(t) \leq \emptyset)\}$. This is by definition equivalent to $\text{row}(t)\sigma \leq_n \emptyset$, thus $\text{row}(t\sigma) \leq_n \emptyset$ and by Lemma C.5 $t\sigma \leq_{n+1} \emptyset$, which concludes $\sigma \Vdash_{n+1} \{(t \leq \emptyset)\}$.

(NROW) The result is direct if $\mathcal{S} = \emptyset$. Otherwise, we have $C' = \bigcup_{\iota \in N \rightarrow L \cup \{_ \}}$ C'_ι , where $C'_\iota \in \bigsqcup_{\ell \in L} \mathcal{S}'_\ell \sqcup \bigsqcup_{N' \in N} \mathcal{S}'_{N'}$. For all $\iota : N \rightarrow L \cup \{_ \}$, there are two cases.

(1) In the first case, there is $\ell \in L$ such that $C'_\iota \in \mathcal{S}'_\ell$. Then, by induction,

$$\sigma \Vdash_n \left\{ \left(\bigwedge_{r \in P} r[\ell] \wedge \bigwedge_{r \in \iota^{-1}(\ell)} \neg r[\ell] \leq \emptyset \right) \right\}$$

(2) In the second case, we have $C'_\iota = \bigcup_{N'} C'_\iota^{N'}$, where $C'_\iota^{N'} \in \mathcal{S}'_{N'}$. For all N' , there are two subcases.

(a) In the first subcase, $N' \in N$. Then, by induction,

$$\sigma \Vdash_n \left\{ \left(\bigwedge_{r \in P} r \setminus^\Delta L \wedge \bigwedge_{r \in \iota^{-1}(_) \setminus N'} \neg(r \setminus^\Delta L) \leq \emptyset \right) \right\}$$

(b) In the second subcase, $N' \in \iota^{-1}(_) \cap N_\Delta \setminus N$. Then we have

$$\sigma \Vdash_n \left\{ \left(\bigwedge_{r \in P_\Delta} \langle \text{lab}(r) \mid \text{tail}(r) \rangle \wedge \bigwedge_{r \in N'} \neg \langle \text{lab}(r) \mid \text{tail}(r) \rangle, \leq, \emptyset \right) \right\}$$

In other words, $\forall \iota : N \rightarrow L \cup \{_ \}. \forall N' \subseteq \iota^{-1}(_) \cap N_\Delta :$

$$\left(\exists \ell \in L. \bigwedge_{r \in P} r[\ell]\sigma \leq_n \bigvee_{r \in \iota^{-1}(\ell)} r[\ell]\sigma \right) \text{ or } \left(\bigwedge_{r \in P} (r \setminus^\Delta L)\sigma \leq_n \bigvee_{r \in \iota^{-1}(_) \setminus N'} (r \setminus^\Delta L)\sigma \right)$$

$$\text{ or } \left(\bigwedge_{r \in P_\Delta} \langle \text{lab}(r) \mid \text{tail}(r) \rangle \wedge \bigwedge_{r \in N'} \neg \langle \text{lab}(r) \mid \text{tail}(r) \rangle \right)$$

Let $P_0 = \{r \in P \mid \text{tail}(r) = \rho \notin \Delta \text{ and } \text{def}(\rho) \cap L \neq \emptyset\}$, same for N_0 . By Lemma C.4, the definition of substitution and the fact that $r[\ell] = r(\ell)$ and $r \setminus^\Delta L = r \setminus L$ for all $r \notin P_0 \cup N_0$, we have $\text{marsh}(r_0, L, \Delta)\sigma \leq_n \emptyset$, that is $\sigma \Vdash \{\text{marsh}(r_0, L, \Delta), \leq, \emptyset\}$. By Lemma C.7, we conclude $\sigma \Vdash_n \{(r_0 \leq \emptyset)\}$.

(NTAIL-MONO) The result is direct if $\prod_{\iota \in I} \sqcup_{\ell \in L} \mathcal{S}_\ell^\iota = \emptyset$. Otherwise, we have $C' = \bigcup_{\iota \in I} C'_\iota$, where $\mathcal{S}'_\iota \in \sqcup_{\ell \in L} \mathcal{S}_\ell^\ell$. By definition of \sqcup , for all $\iota \in I$, there is $\ell \in L$ such that $C'_\iota \in \mathcal{S}_\ell^\ell$. By induction, $\sigma \Vdash_n \{(\bigwedge_{r \in P} r(\ell) \wedge \bigwedge_{r \in \iota^{-1}(\ell)} \neg r(\ell))\}$. In other words,

$$\forall \iota \in I. \exists \ell \in L. \bigwedge_{r \in P} r(\ell)\sigma \wedge \bigwedge_{r \in \iota^{-1}(\ell)} \neg r(\ell)\sigma \leq_n \emptyset$$

Moreover, by hypothesis that $L \subseteq \bigcup_{r \in P \cup N} \text{lab}(r)$. Also, for each $\iota \notin I$, one of the two conditions (10) or (11) of Lemma A.6 is satisfied. By this corollary, $\bigwedge_{r \in P} r\sigma \wedge \bigwedge_{r \in N} \neg r\sigma \leq_n \emptyset$. We conclude $\sigma \Vdash_n \{(\bigwedge_{r \in P} r \wedge \bigwedge_{r \in N} \neg r \leq \emptyset)\}$.

(NTAIL-TLV) Let $r_0 = \bigwedge_{r \in P} r \wedge \bigwedge_{r \in N} r$. By hypothesis, there is $r' = \langle \mathbb{1} \rho \setminus L_1 \rangle^{L_2} \in P \cup N$ such that $\rho \not\leq_O r'$. There are two similar cases, we detail the one where $r' \in P$. Let $r'_0 = \bigwedge_{r \in P \setminus \{r'\}} \neg r \wedge \bigwedge_{r \in N} r$. By hypothesis, we have $\sigma \Vdash_n \{(r'\sigma \leq \neg r'_0)\}$, thus $r'\sigma \leq_n r'_0\sigma$. This is equivalent to $r_0\sigma \leq_n \emptyset$, and we conclude $\sigma \Vdash_n \{(r_0 \leq \emptyset)\}$. \square

We introduce a notion of plinth generalizing the one of Frisch [20] to types, field-types and rows. This notion is used to prove termination of the algorithm.

DEFINITION C.11 (PLINTH). A plinth $\sqsupset \subset \mathcal{T}_\perp \cup \mathcal{R}$ is a set of types, field-types and rows with the following properties:

- \sqsupset is finite;
- \sqsupset contains $\emptyset, \mathbb{1}, \perp, \langle \mathbb{1} \cdot \rangle^0$ and is closed under Boolean connectives (\vee, \wedge, \neg);
- for all type $t_1 \rightarrow t_2 \in \sqsupset$, we have $t_1 \in \sqsupset$ and $t_2 \in \sqsupset$;
- for all type $R \in \sqsupset$, we have $\text{row}(R) \in \sqsupset$;
- for all row $r \in \sqsupset$ of definition space $\mathcal{L} \setminus L_r$, let L be the set of labels appearing explicitly in \sqsupset and V the set of row variables in \sqsupset , we have:
 - for all $\ell \in L$, $r(\ell) \in \sqsupset$
 - for all $L' \subseteq L, \forall V' \subseteq V, r \setminus^{V'} L' \in \sqsupset$ and $\text{marsh}(r, L', V') \in \sqsupset$.

Every finite set of types, field-types and types is included in a plinth. Indeed, for a regular type t , the set of its subtrees S is finite, while rows and field-types are inductively defined. The definition of the plinth ensures that the closure of S under Boolean connectives is also finite. Moreover, if a type, field-type or row belongs in a plinth, the set of its subtrees also does. Finally, if a record or a row belongs to a plinth, the rows obtained by marshalling or by removing fields also belongs to the plinth, but only if these operations are done with respect to the set of labels present in the plinth, in order to guarantee finiteness of the plinth.

LEMMA C.9 (TERMINATION). Let C be a finite constraint set. The normalization of C terminates.

PROOF. Let B be the set of types occurring in C . As C is finite, B is finite as well. Let \sqsupset be a plinth such that $B \subseteq \sqsupset$. Then, when we normalize a constraint (t, \leq, \emptyset) during the process of $\emptyset \vdash_N C$, t would belong to \sqsupset . We prove the lemma by induction on $(|\sqsupset \setminus \Sigma|, U, |C|)$, U is the number of unions \vee occurring in the constraint-set C (over any kind) plus the number of constraints (T_1, \leq, T_2) where $T_2 \neq \emptyset$ or T_1 is not in DNF, and C is the constraint-set to be normalized. We detail the original cases, others are described in the proof [10, Lemma C.14].

(NOPT) Terminates immediately.

(NREC) None of the indices decreases, but the next rule to apply must be one of (NROW), (NTAIL-MONO) or (NTAIL-TLV).

(NROW) Although $(|\sqsupset \setminus \Sigma|, U, |C|)$ may not change, the next rule to apply must be one of (NDNF), (NHYP), (NASSUM), (NTLV), (NOPT) for \mathcal{S}_ℓ^i and (NTAIL-TLV) for $\mathcal{S}_{N'}^i$.

(NTAIL-MONO) Although $(|\sqsupset \setminus \Sigma|, U, |C|)$ may not change, the next rule to apply must be one of (NDF), (NHY), (NASSUM), (NTLV), (NOPT).

(NTAIL-TLV) Terminates immediately. \square

DEFINITION C.12 (NORMALIZED CONSTRAINT). A constraint is said to be normalized if it is of the shape (X, c, T) , where X and T are of the same kind. A constraint-set is normalized if all constraints are.

LEMMA C.10. Let C be a constraint-set and $\emptyset \vdash_N C \rightsquigarrow \mathcal{S}$. Then, all constraint-sets $C' \in \mathcal{S}$ are normalized.

PROOF. Straightforward by induction on the algorithm derivation. \square

LEMMA C.11 (FINITENESS). Let C be a constraint-set and $\emptyset \vdash_N C \rightsquigarrow \mathcal{S}$. Then, \mathcal{S} is finite.

PROOF. It is easy to prove that each normalizing rule generates a finite set of finite sets of normalized constraints. \square

DEFINITION C.13. Let C be a normalized constraint-set and O an ordering on $\text{vars}(C)$ and on the labels occurring in C . We say C is well-ordered if for all normalized constraint $(X_1, c, T) \in C$ and for all $X_2 \in \text{tlv}(T)$, $O(X_1) < O(X_2)$ holds.

LEMMA C.12. Let C be a constraint-set and $\emptyset \vdash_N C \rightsquigarrow \mathcal{S}$. Then for all normalized constraint-set $C' \in \mathcal{S}$, C' is well-ordered.

PROOF. There are two different ways to generate normalized constraints:

(NTLV) We single out the type variable X' whose order is minimum, because $\text{tlv}(T) = \emptyset$.

(NTAIL-TLV) We single out the row variable ρ whose order is minimum. \square

C.5 Constraint Merging and Saturation

After normalization, we have a set of constraint-sets where the same variable might have several upper and lower bounds given by different constraints on that variable. After this step, we wish to obtain unique upper and lower bounds for the same variable. This is done in two phases. For each normalized constraint-set C and following the order on variables, we:

- Merge two constraints (X, \leq, T_1) and (X, \leq, T_2) into $(X, \leq, T_1 \wedge T_2)$.
- Merge two constraints (X, \geq, T_1) and (X, \geq, T_2) into $(X, \geq, T_1 \vee T_2)$.

Once the set C has been transformed into C' where there are no such constraints left, we saturate the set to verify that the lower bound is indeed a subtype of the upper bound, once again following the order on variables. From two constraints (T_1, \leq, X) and (X, \leq, T_2) , we normalize the constraint $(T_1 \wedge \neg T_2, \leq, \emptyset)$. We obtain a set of constraint-sets \mathcal{S} . We add the new resulting constraint-sets accordingly to the existing ones with $\mathcal{S} \sqcap \{C'\}$, then apply the step of merging and saturation again on each constraint-sets in $\mathcal{S} \sqcap \{C'\}$. Termination of this step is assured as in the step of constraint normalization by an additional argument M to the merge function, saving visited types.

Formally, this part is almost exactly the same as in the original algorithm in [10, Section C.1.2]. One simply needs to replace occurrences of α and t by the more general meta-variables X and T . The rules are given in Figs. 8 and 9. Termination is proved thanks to the generalized definition of plinths (Definition C.11).

$$\begin{array}{c}
\forall \iota : N \rightarrow L \cup \{_ \}. \left\{ \begin{array}{l}
\forall \ell \in L. \Sigma \vdash_N \{ (\bigwedge_{r \in P} r[\ell] \wedge \bigwedge_{r \in \iota^{-1}(\ell)} \neg r[\ell], \leq, \emptyset) \} \rightsquigarrow \mathcal{S}'_\ell \\
\forall N' \in \mathcal{N}. \Sigma \vdash_N \{ (\bigwedge_{r \in P} r \setminus^\Delta L \wedge \bigwedge_{r \in \iota^{-1}(_) \setminus N'} \neg (r \setminus^\Delta L), \leq, \emptyset) \} \rightsquigarrow \mathcal{S}'_{N'} \\
\rho \not\leq \text{tlv}(r_0) \quad \rho \notin \Delta \quad L = \text{def}(r_0) \setminus \text{def}(\rho) \quad L \neq \emptyset \\
P_\Delta = \{ r \in P \cap \Delta \mid \text{tail}(r) = \rho_p \text{ and } \text{def}(\rho_p) \cap L \neq \emptyset \} \\

Fig. 9. Saturation rules

C.6 Harmonization

Thanks to the last step, we now have a set of constraint-sets such that in all constraint-sets, each variable in the domain of the constraint-set has at most one upper bound and one lower bound. Yet, for a row variable ρ of the original type constraints, we can have several constraints for the derived constructors $\rho \setminus L$, for instance a constraint-set containing both $(\rho \setminus L_1, \leq, T_1)$ and $(\rho \setminus L_2, \leq, T_2)$, with $L_1 \cap \text{def}(\rho) \neq L_2 \cap \text{def}(\rho)$. There could also be occurrences of another construction $\rho \setminus L_3$ in T_1 with a different L_3 . We want a unique decomposition of ρ in each constraint-set, with a unique set L_0 such that only $\rho \setminus L_0$ may appear in the domain of the constraint-set. From this, we will build a solution such that $\sigma(\rho) \simeq (\ell = \tau_\ell)_{\ell \in L_0} r$. There can be occurrences of $\rho \setminus L'$ not in the domain, or of $\rho \cdot \ell'$, but substitution will be correctly defined since we take L_0 to cover all such occurrences.

Formally, a harmonized constraint is defined as follow.

DEFINITION C.14 (HARMONIZED CONSTRAINT). *Let $C \subseteq \mathcal{C}$ be a saturated constraint-set. We say C is harmonized if for each type variable $\rho \in \text{dom}(C)$, there is a finite set of labels L such that:*

- (1) $\forall (\rho \setminus L_i, c, r_i) \in C. L_i \setminus \text{def}(\rho) = L \setminus \text{def}(\rho)$;
- (2) $\forall \rho \setminus L' \in \text{vars}(C). L' \subseteq L$;
- (3) $\forall \rho \cdot \ell \in \text{vars}(C). \ell \in L \cap \text{def}(\rho)$.

If a constraint-set is not harmonized, then it is of the shape $C \cup \{(\rho \setminus L)^L, c, r\}$, where $L_0 \not\subseteq L$, when we define $L_0 = \bigcup_{\rho \cdot \ell \in \text{vars}(C) \cup \text{vars}(r)} \{\ell\} \cup \bigcup_{\rho \setminus L' \in \text{vars}(C) \cup \text{vars}(r)} L'$. To harmonize the decomposition of the variable row, we normalize the constraint-set $\{(\ell = \rho \cdot \ell)_{\ell \in L_0 \setminus L} (\rho \setminus L_0)^L, c, r\}$. We integrate the obtained set of constraint-sets \mathcal{S} to the existing constraints with $\{C\} \sqcap \mathcal{S}$ and apply merging and harmonization recursively. The rules are given in Fig. 10.

LEMMA C.13 (SOUNDNESS). *Let C be a finite saturated constraint-set. If $\emptyset \vdash_H C \rightsquigarrow \mathcal{S}$, then for all constraint-set $C' \in \mathcal{S}$ and all substitution σ , we have $\sigma \Vdash C' \implies \sigma \Vdash C$.*

PROOF. The proof is by induction on the derivation tree. We prove the more general statement for all Σ . The base case $\Sigma \vdash_H C \rightsquigarrow \{C\}$ is trivial. In the inductive case, let $C = C_0 \cup \{(\rho \setminus L)^L, c, r\}$. By definition of \sqcup , there are $C_n \in \{C\} \sqcap \mathcal{S}$ and $C_m \in \mathcal{S}_n$ such that $C' \in \mathcal{S}_n^m$. Since $\sigma \Vdash C'$, we have by induction hypothesis on $\Sigma \cup C_m \vdash_H C_m \rightsquigarrow \mathcal{S}_n^m$ that $\sigma \Vdash C_m$. By definition of \sqcup again, there is $C_n \in \{C_0\} \sqcap \mathcal{S}$ such that $C_m \in \mathcal{S}_n$. Since $\sigma \Vdash C_m$, we have by soundness of constraint merging on

$$\begin{array}{c}
\frac{C \text{ is harmonized}}{\Sigma \vdash_{\mathcal{H}} C \rightsquigarrow \{C\}} \text{ (HDONE)} \\
\\
L_0 = \bigcup_{\rho, \ell \in \text{vars}(C) \cup \text{vars}(r)} \{\ell\} \cup \bigcup_{\rho \setminus L' \in \text{vars}(C) \cup \text{vars}(r)} L' \quad L_0 \not\subseteq L \\
\emptyset \vdash_{\mathcal{N}} \{ \langle (\ell = \rho.\ell)_{\ell \in L_0 \setminus L} \mid \rho \setminus L_0 \rangle^L, c, r \} \rightsquigarrow \mathcal{S} \\
\forall C_n \in \{C\} \cap \mathcal{S}. (\emptyset, \emptyset \vdash_{\text{MS}} C_n \rightsquigarrow \mathcal{S}_n) \\
\forall C_m \in \mathcal{S}_n \text{ and } C_m \notin \Sigma. (\Sigma \cup C_m \vdash_{\mathcal{H}} C_m \rightsquigarrow \mathcal{S}_n^m) \\
\hline
\Sigma \vdash_{\mathcal{H}} C \cup \{ \langle (\rho \setminus L) \rangle^L, c, r \} \rightsquigarrow \bigsqcup_{C_n \in \{C\} \cap \mathcal{S}} \bigsqcup_{C_m \in \mathcal{S}_n} \mathcal{S}_n^m \text{ (HARM)}
\end{array}$$

Fig. 10. Harmonization rules

$\emptyset, \emptyset \vdash_{\text{MS}} C_n \rightsquigarrow \mathcal{S}_n$ that $\sigma \Vdash C_n$. We have $C_n = C_0 \cup C'_n$ with $C'_n \in \mathcal{S}$. Since $\sigma \Vdash C_n$, we have $\sigma \Vdash C'_n$ and by Lemma C.8 $\sigma \Vdash \{ \langle (\ell = \rho.\ell)_{\ell \in L_0 \setminus L} \mid \rho \setminus L_0 \rangle^L, c, r \}$. Thus, $\sigma(\rho) \simeq \langle (\ell = \tau_\ell)_{\ell \in L \cap \text{def}(\rho)}, (\ell = \tau_\ell)_{\ell \in L_0 \setminus L} \mid r' \rangle^{\mathcal{L} \setminus \text{def}(\rho)}$. Then, $\langle (\ell = \rho.\ell)_{\ell \in L_0 \setminus L} \mid \rho \setminus L_0 \rangle^L \sigma = \langle (\rho \setminus L) \rangle^L \sigma = \langle (\ell = \tau_\ell)_{\ell \in L_0 \setminus L} \mid r' \rangle^L$. Therefore, $\sigma \Vdash \{ \langle (\rho \setminus L) \rangle^L, c, r \}$. We conclude $\sigma \Vdash C_0$ as well because $\sigma \Vdash C_n$ and $C_0 \subseteq C_n$. \square

LEMMA C.14 (TERMINATION). *Let C be a finite saturated constraint-set. The harmonization of C terminates.*

PROOF. Let B be the set of types, type fields and rows in C , finite since C is finite. Let \sqsupseteq be a plinth such $B \subseteq \sqsupseteq$. When adding a set of constraint C_m to Σ during harmonization, every constraint of C_m belongs to $(\sqsupseteq \times \{\leq, \geq\} \times \sqsupseteq)$. The proof is by induction on $(|\{\sqsupseteq \times \{\leq, \geq\} \times \sqsupseteq\}| - |\Sigma|, |C|)$ lexicographically ordered.

(HDONE) Terminates immediatly.

(HARM) Normalization, merging and saturation all terminate. In the recursive step of harmonization that are applied, $(|\{\sqsupseteq \times \{\leq, \geq\} \times \sqsupseteq\}| - |\Sigma|)$ decreases. \square

LEMMA C.15 (FINITENESS). *Let C be a finite saturated constraint-set and $\emptyset \vdash_{\mathcal{H}} C \rightsquigarrow \mathcal{S}$. Then \mathcal{S} is finite.*

PROOF. By induction on the derivation and by Lemma C.11 and finiteness of constraint merging. \square

LEMMA C.16. *Let C be a finite saturated constraint-set and $\vdash_{\mathcal{H}} C \rightsquigarrow \mathcal{S}$. Then for all constraint-set $C' \in \mathcal{S}$, C' is harmonized.*

PROOF. Direct by induction on the derivation, finite by Lemma C.14. \square

LEMMA C.17. *Let C be a well-ordered saturated constraint-set and $\emptyset \vdash_{\mathcal{H}} C \rightsquigarrow \mathcal{S}$. Then for all harmonized constraint-set $C' \in \mathcal{S}$, C' is well-ordered.*

PROOF. Consequence of Lemma C.12 and conservation of well-orderedness by merging and saturation. \square

C.7 From Constraints to Equations

Once normalization, merging and harmonization are done, we have a set of well-ordered constraint-sets at hand, where all variables have unique lower and upper bounds, and for each row variable ρ ,

there is at most a unique occurrence of $\rho \setminus L$ (where L can be empty if ρ has not been decomposed), such that also every occurrence of $\rho.\ell$ has $\ell \in L$. We are now able to rewrite each constraint-set C into an equivalent equation system.

DEFINITION C.15 (EQUATION SYSTEM). *An equation system E is a set of equations of the form $X = T$ such that there exists at most one equation in E for every variable X , and X and T are of the same kind. We define the domain of E , written $\text{dom}(E)$, as the set $\{X \mid \exists T. X = T \in E\}$.*

DEFINITION C.16 (EQUATION SYSTEM SOLUTION). *Let E be an equation system. A solution to E is a substitution σ such that $\forall (X = T) \in E. \sigma(X) \simeq T\sigma$ holds. If σ is a solution to E , we write $\sigma \Vdash E$.*

Given a constraint-set C , we will use the notation $(T_1 \leq X \leq T_2) \in C$ to indicate $\{(T_1, \leq, X), (X, \leq, T_2)\} \subseteq C$. We assume that every variable and every term $\rho.\ell$, $\rho \setminus L$ in $\text{dom}(C)$ have an upper and a lower bound, without loss of generality because a constraint with bottom or top types can always be added if needed:

- For a type variable α , we can add constraints $(0, \leq, \alpha)$ or $(\alpha, \leq, \mathbb{1})$;
- For a field variable θ (or $\rho.\ell$), we can add constraints $(0, \leq, \theta)$ or $(\theta, \leq, \mathbb{1} \vee \perp)$;
- For a row variable $\rho \setminus L$ (or ρ), we can add constraints $(0, \leq, \rho \setminus L)$ or $(\rho \setminus L, \leq, \langle \mathbb{1} \dots \rangle^{\mathcal{L} \setminus (\text{def}(\rho) \cup L)})$.

We rewrite the set C to a set of equations with a function $\text{solve}(C)$, where α' , θ' , θ_ℓ and ρ' are fresh variables. We write $(T_1 \leq X \leq T_2)$ for the constraints $\{(T_1, \leq, X), (X, \leq, T_2)\} \subseteq C$.

$$\begin{aligned} \text{solve}(C) = & \{ \alpha = (t_1 \vee \alpha') \wedge t_2 \mid (t_1 \leq \alpha \leq t_2) \in C \} \\ & \cup \{ \theta = (\tau_1 \vee \theta') \wedge \tau_2 \mid (\tau_1 \leq \theta \leq \tau_2) \in C \text{ and } \theta \neq \rho.\ell \} \\ & \cup \{ \rho = \langle (\ell = \tau_\ell)_{\ell \in L} \mid r \rangle^{\mathcal{L} \setminus \text{def}(\rho)} \\ & \quad \mid (\text{if } \exists L'. (r_1 \leq \rho \setminus L' \leq r_2) \in C, \text{ then } L = L' \cap \text{def}(\rho) \text{ and } r = (r_1 \vee \rho') \wedge r_2, \\ & \quad \text{else } L = \{ \ell \mid \rho.\ell \in \text{vars}(C) \} \text{ and } r = \rho' \} \\ & \quad \text{and } (\forall \ell \in L. \text{if } (\tau_\ell^1 \leq \rho.\ell \leq \tau_\ell^2) \in C \text{ then } \tau_\ell = (\tau_\ell^1 \vee \theta_\ell) \wedge \tau_\ell^2 \text{ else } r = \theta_\ell) \} \end{aligned}$$

where α' , θ' , and ρ' are fresh variables.

For type and field variables (not generated by the decomposition of a row variable), we obtain an equation by means of the type connectives, where the union entails a lower bound and the intersection an upper bound. For a row variable ρ , there is L and constraints $(\tau_\ell^1 \leq \rho.\ell \leq \tau_\ell^2) \in C$ for all $\ell \in L$ and $(r_1 \leq \rho \setminus L \leq r_2)$, with the potentially missing constraints obtained with the default values. Since we have decomposed ρ into the labels in L and a part of definition space $\mathcal{L} \setminus (\text{def}(\rho) \cup L)$, we build an equation for ρ by concatenating the independent types for $\rho.\ell$ and $\rho \setminus L$ together.

To prove soundness of the transformation, we define the rank n satisfaction predicate \Vdash_n for equation systems, which is similar to the one for constraint-sets.

LEMMA C.18 (SOUNDNESS). *Let $C \subseteq C$ be a well-ordered saturated constraint-set and E its transformed equation system. Then for all substitutions σ , if $\sigma \Vdash E$, then $\sigma \Vdash C$.*

PROOF. We write $O(C_1) < O(C_2)$ if $O(X_1) < O(X_2)$ for all $X_1 \in \text{dom}(C_1)$ and all $X_2 \in \text{dom}(C_2)$. We prove a stronger statement:

(*) For all σ , n and $C_\Sigma \subseteq C$, if $\sigma \Vdash_n E$, $\sigma \Vdash_n C_\Sigma$, $\sigma \Vdash_{n-1} C \setminus C_\Sigma$ and $O(C \setminus C_\Sigma) < O(C_\Sigma)$, then $\sigma \Vdash_n C \setminus C_\Sigma$.

Here C_Σ denotes the set of constraints that have been checked. The proof proceeds by induction on $|C \setminus C_\Sigma|$, and is similar to the proof of [10, Lemma C.33] for type variables only. The base case $C \setminus C_\Sigma = \emptyset$ is straightforward. Let $C \setminus C_\Sigma \neq \emptyset$ and let us consider the case of row variables. Take

ρ with the maximal order in $\text{dom}(C \setminus C_\Sigma)$. There are a set L and corresponding equations $\rho \setminus L = r = (r_1 \wedge \rho') \wedge r_2$ and $(\rho.\ell = \tau_\ell = (\tau_\ell^1 \vee \theta_\ell) \wedge \tau_\ell^2)_{\ell \in L}$. As $\sigma \Vdash_n E$, we have $\sigma(\rho) \simeq_n \langle (\ell = \tau_\ell \mid r)^{L_\rho} \sigma \rangle$, where $L_\rho = \mathcal{L} \setminus \text{def}(\rho)$. Then, for all $\ell \in L$:

$$(\rho.\ell)\sigma \wedge \neg\tau_\ell^2\sigma \simeq_n ((\tau_\ell^1 \vee \theta_\ell) \wedge \tau_\ell^2)\sigma \wedge \neg\tau_\ell^2\sigma \simeq_n \emptyset$$

And similarly for $(\rho \setminus L)\sigma \wedge \neg(\rho \setminus L)\sigma$. On the other hand, for all $\ell \in L$, we have:

$$\tau_\ell^1\sigma \wedge \neg(\rho.\ell)\sigma \simeq_n \tau_\ell^1 \wedge \neg((\tau_\ell^1 \vee \theta_\ell) \wedge \tau_\ell^2)\sigma \simeq_n \tau_\ell^1\sigma \wedge \neg\tau_\ell^2\sigma$$

And similarly for $r_1\sigma \wedge \neg(\rho \setminus L)\sigma$. It remains to show that $\tau_\ell^1\sigma \leq_n \tau_\ell^2\sigma$ holds for all $\ell \in L$ and that $r_1\sigma \leq_n r_2\sigma$ hold, that is $\sigma \Vdash_n \{(\tau_\ell^1 \leq \tau_\ell^2)_{\ell \in L}, (r_1 \leq r_2)\}$. The rest of the proof goes as in [10, Lemma C.33]. We use the fact that the order of $\rho.\ell$ and $\rho \setminus L$ is directly superior to the order of ρ , and thus maximal in $\text{dom}(C \setminus C_\Sigma)$. \square

LEMMA C.19 (COMPLETENESS). *Let $C \subseteq C$ be a saturated normalized constraint-set and E its transformed equation system. Then for all substitution σ , if $\sigma \Vdash C$, there exists σ' such that $\text{dom}(\sigma') \cup \text{dom}(\sigma) = \emptyset$ and $\sigma \cup \sigma' \Vdash E$.*

PROOF. Let $\sigma' = \{\sigma(\alpha)/\alpha' \mid \alpha \in \text{dom}(C)\} \cup \{\sigma(\theta)/\theta' \mid \theta \in \text{dom}(C) \text{ and } \theta \neq \rho.\ell\} \cup \{(\rho \setminus L)\sigma/\rho'\} \cup \{(\rho.\ell)\sigma/\theta_\ell^0 \mid \rho.\ell \in \text{dom}(C)\}$, where L is obtained as in the definition of solve either from $\rho \setminus L' \in \text{dom}(C)$ and $L = L' \cap \text{def}(\rho)$, or by $L = \{\ell \mid \rho.\ell \in \text{vars}(C)\}$. The case for type and field variables is as in [10, Lemma C.34]. Let us consider an equation $\rho = \langle (\ell = \tau_\ell)_{\ell \in L} \mid r \rangle^{\mathcal{L} \setminus \text{def}(\rho)} \in E$. Correspondingly, there exist $(r_1 \leq \rho \setminus L \leq r_2) \in C$ and for all $\ell \in L$, there exist $(\tau_\ell^1 \leq \rho.\ell \leq \tau_\ell^2) \in C$ (without loss of generality, we suppose C to be saturated with default values). As $\sigma \Vdash C$, then $r_1\sigma \leq (\rho \setminus L)\sigma \leq r_2\sigma$, and for all $\ell \in L$, $\tau_\ell^1\sigma \leq (\rho.\ell)\sigma \leq r_2\sigma$, and the operations $(\rho \setminus L)\sigma$ and $(\rho.\ell)\sigma$ are defined. Thus,

$$\begin{aligned} \langle (\ell = \tau_\ell)_{\ell \in L} \mid r \rangle (\sigma \cup \sigma') &= \langle (\ell = (\tau_\ell^1(\sigma \cup \sigma') \vee (\sigma \cup \sigma')(\theta_\ell^0)) \wedge \tau_\ell^2(\sigma \cup \sigma'))_{\ell \in L} \mid \\ &\quad (r_1(\sigma \cup \sigma') \vee (\sigma \cup \sigma')(\rho')) \wedge r_2(\sigma \cup \sigma') \rangle \\ &= \langle (\ell = (\tau_\ell^1\sigma \vee (\rho.\ell)\sigma) \wedge \tau_\ell^2\sigma)_{\ell \in L} \mid (r_1\sigma \vee (\rho \setminus L)\sigma \wedge r_2\sigma) \rangle \\ &\simeq \langle (\ell = (\rho.\ell)\sigma \wedge \tau_\ell^2\sigma)_{\ell \in L} \mid (\rho \setminus L)\sigma \wedge r_2\sigma \rangle \\ &\simeq \langle (\ell = (\rho.\ell)\sigma)_{\ell \in L} \mid (\rho \setminus L)\sigma \rangle \\ &= \sigma(\rho) \end{aligned}$$

The last line is justified by σ being a solution to C , so being of the shape $\sigma(\rho) = \langle (\ell = \tau_\ell')_{\ell \in L} \mid r' \rangle$. \square

DEFINITION C.17. *Let E be an equation system and O an ordering on $\text{dom}(E)$ and on the labels occurring in E . We say that E is well-ordered if for all $X = T_X \in E$ and $X' \in \text{tlv}(T_X) \cap \text{dom}(E)$, we have $O(X_1) < O(X')$.*

LEMMA C.20. *Let C be a well-ordered saturated normalized constraint-set and E its transformed equation system. Then E is well-ordered.*

PROOF. We have $\text{dom}(E) = \text{dom}(C) \cap (\mathcal{V}_t \cup \mathcal{V}_f) \cup \{\rho \mid \exists \ell.\rho.\ell \in \text{dom}(C) \text{ or } \exists L.\rho \setminus L \in \text{dom}(C)\}$. The case for type and field variables is as in [10, Lemma C.36], but uses the fact that $(\text{tlv}(T_1) \cup \text{tlv}(T_2)) \cap \text{dom}(E) = (\text{tlv}(T_1) \cup \text{tlv}(T_2)) \cap \text{dom}(C)$. Now, consider $\rho = r_0$ with $r_0 = \langle (\ell = \tau_\ell)_{\ell \in L} \mid r \rangle$ obtained from $(r_1 \leq \rho \setminus L \leq r_2) \in C$ with $r = (r_1 \wedge \rho') \vee r_2$, and for all $\ell \in L$ from $(\tau_\ell^1 \leq \rho.\ell^2) \in C$. We have $\text{tlv}(r_0) = \text{tlv}(r)$. Since C is well-ordered, for all $(\rho_2 \in \text{tlv}(r_1) \cup \text{tlv}(r_2)) \cap \text{dom}(C)$, $O(\rho) < O(\rho_2)$. Moreover, ρ' is a fresh row variable in C , that is $\rho' \notin \text{dom}(C)$. And then $\rho' \notin \text{dom}(E)$. Therefore, $\text{tlv}(r) \cap \text{dom}(E) = (\text{tlv}(r_1) \cup \text{tlv}(r_2)) \cap \text{dom}(C)$ and the result follows. \square

C.8 Solution of Equation Systems

We have now obtained a set of equation-sets E , that we must each transform into a substitution σ . We do this in the same way as in [10, §3.2.2], but with all kinds of variables rather than just type variables. In the set of equations, there is no construction $\rho.t$ or $\rho \setminus L$ anymore. We define a function $\text{Unify}(E)$ as $\text{Unify}(\emptyset) = \{\}$, and otherwise:

- (1) Select in E the equation $X = T$ for the smallest X w.r.t. the order;
- (2) Let E' be the set of equations obtained by replacing in $E \setminus \{X = T\}$ every occurrence of X by $\mu X'.(T\{X'/X\})$ (X' fresh);
- (3) Let $\sigma = \text{Unify}(E')$ and return $\{X = (\mu X'.T\{X'/X\})\sigma\} \cup \sigma$.

The ordering on the variables guarantees the regularity of the obtained types. For the elements $\sigma(X) = \mu X'.T$ where $X' \notin \text{vars}(T)$, we can remove the introduced μ -abstraction.

It is straightforward to extend the proofs and definitions.

DEFINITION C.18 (GENERAL SOLUTION). *Let E be an equation system. A general solution to E is a substitution σ from $\text{dom}(E)$ to $\mathcal{T}_\perp \cup \mathcal{R}$ such that $\forall X \in \text{dom}(\sigma). \text{vars}(\sigma(X)) \cap \text{dom}(\sigma) = \emptyset$ and $\forall X = T \in E. \sigma(X) \simeq T\sigma$ holds.*

DEFINITION C.19 (EQUIVALENT SUBSTITUTIONS). *Let σ, σ' be two substitutions. We say $\sigma \simeq \sigma'$ if and only if $\forall X. \sigma(X) \simeq \sigma'(X)$.*

PROPOSITION C.21. *Let E be a well-ordered equation system. Let $\text{Unify}(E)$ be the procedure described by Castagna et al. [10] to build a substitution.*

Soundness *If $\sigma = \text{Unify}(E)$, then $\sigma \Vdash E$.*

Completeness *For all substitution σ , if $\sigma \Vdash E$, then there exist σ_0 and σ' such that $\sigma_0 = \text{Unify}(E)$ and $\sigma \simeq \sigma' \circ \sigma_0$.*

Termination *The algorithm $\text{Unify}(E)$ terminates.*

The last property we verified is well-formedness. As in [10], a type is well-formed if and only if the recursion traverses a constructor, and this property is guaranteed thanks to the order on variables.

PROPOSITION C.22 (WELL-FORMEDNESS). *If $\sigma = \text{Unify}(E)$, then for all $X \in \text{dom}(\sigma)$, $\sigma(X)$ is well-formed.*

PROOF. Assume that there exists an ill-formed $\sigma(X)$. That is, $\sigma(X) = \mu x.t$ where x occurs at the top-level of t . According to the algorithm $\text{Unify}()$, there exists a sequence of equations $(X =)X_0 = T_{X_0}, \dots, X_n = T_{X_n}$ such that X_i is at top-level in $T_{X_{i-1}}$ and X_0 is at top-level in T_{X_n} and where $i \in \{1, \dots, n\}$ and $n \geq 0$. We must necessarily have all the X_i of the same kind. Indeed, for type (resp. row) variables only types (resp. row) variables can appear at top-level. Now, if X_0 is a field variable, there can be a type variable X_i at top-level in the field-type T_{i-1} . But then, X_0 cannot be at top-level in X_n since T_i is a type, and field variables cannot appear at top-level in a type. Since all X and T must be of the same kind and according to [Definition C.17](#), we have $O(X_{i-1}) < O(X_i)$ and $O(X_n) < O(X_0)$. Therefore, we have $O(X_0) < O(X_1) < \dots < O(X_n) < O(X_0)$, which is impossible. Thus the result follows. \square

C.9 The Complete Algorithm

The procedure $\text{Sol}_\Delta(C)$ to solve type tallying of a constraint-set C proceeds as follows.

- (1) C is normalized into a finite set \mathcal{S} of well-ordered normalized constraint-sets ([Appendix C.4](#)).
- (2) Each constraint-set $C_i \in \mathcal{S}$ is merged and saturated into a finite set \mathcal{S}_{C_i} of well-ordered constraint-sets. Then, all these sets are collected into another set \mathcal{S}' (i.e., $\mathcal{S}' = \bigsqcup_{C_i \in \mathcal{S}} \mathcal{S}_{C_i}$) ([Appendix C.5](#)).

- (3) Each constraint-set $C'_i \in \mathcal{S}'$ is harmonized into a finite set $\mathcal{S}_{C'_i}$ of well-ordered harmonized constraint-sets. Then, all these sets are collected into another set \mathcal{S}'' (i.e., $\mathcal{S}'' = \bigsqcup_{C'_i \in \mathcal{S}'} \mathcal{S}_{C'_i}$) (Appendix C.6). This step is specific to row variables.
- (4) For each constraint-set $C''_i \in \mathcal{S}''$, we transform C''_i into an equation system E_i and then construct a general solution σ_i from E_i (Appendix C.7).
- (5) Finally, we collect all the solutions σ_i , yielding a set Θ of solutions to C (Appendix C.8).

In the original algorithm for type variables, failing at the step of normalization means that there is no solution overall, even when increasing the cardinality of the substitution sets sought by dove-tail order in the general algorithm described in the beginning of Section 3.3 (see [10, §3.2.3]). Whether here a failure in the step of normalization or harmonization means the absence of a solution overall is still an open question.

We write $\text{Sol}_\Delta(C) \rightsquigarrow \Theta$ if $\text{Sol}_\Delta(C)$ terminates with Θ , and we call Θ the solution of the type tallying problem for C .

THEOREM 3.6 (SOUNDNESS). *Let C be a constraint-set. If $\text{Sol}_\Delta(C) \rightsquigarrow \Theta$, then for all $\sigma \in \Theta$, $\sigma \Vdash C$.*

PROOF. Consequence of Lemma C.8, soundness of merging, Lemma C.13, Lemma C.18 and soundness of Unify (Proposition C.21). \square

THEOREM 3.7 (TERMINATION). *Let C be a constraint-set. Then $\text{Sol}_\Delta(C)$ terminates.*

PROOF. Consequence of Lemma C.9, termination of merging, Lemma C.14, finiteness of the constraint-sets and termination of Unify (Proposition C.21). \square

PROPOSITION 3.8. *Let C be a constraint-set and $\text{Sol}_\Delta(C) \rightsquigarrow \Theta$. Then (1) Θ is finite and (2) for all $\sigma \in \Theta$ and for all $X \in \text{dom}(\sigma)$, the types in $\sigma(X)$ are contractive.*

PROOF. The first item is a consequence of Lemma C.11, Lemma C.15 and finiteness of the constraints after merging. The second one is a consequence of Lemma C.12, well-orderedness of merging, Lemma C.17, Lemma C.20 and well-orderedness of Unify (Proposition C.21). \square
